Projective completions of Jordan pairs

Part I. The generalized projective geometry of a Lie algebra

Wolfgang Bertram, Karl-Hermann Neeb

Abstract. We prove that the projective completion \((X^+, X^-)\) of the Jordan pair \((g_1, g_{-1})\) corresponding to a 3-graded Lie algebra \(g = g_1 \oplus g_0 \oplus g_{-1}\) can be realized inside the space \(\mathcal{F}\) of inner 3-filtraions of \(g\) in such a way that the remoteness relation on \(X^+ \times X^-\) corresponds to transversality of flags. This realization is used to give geometric proofs of structure results which will be used in Part II of this work in order to define on \(X^+\) and \(X^-\) the structure of a smooth manifold (in arbitrary dimension and over general base fields or \(-\)rings).

Introduction

A basic construction in linear algebra permits to imbed an affine space \(V\) into a projective space \(X\) as the complement of a “hyperplane at infinity” – let us assume here for simplicity that everything is defined over a commutative field \(K\), so that \(X\) may be seen as the projective space \(\mathbb{P}(W)\) with \(W \cong V \oplus K\). In the real or complex case, if the dimension is finite or if \(V\) is e.g. a Banach space, the projective space \(X\) is a smooth manifold with \(V\) as a typical chart domain. An atlas of \(X\) is obtained by taking all affine parts of \(X\) (all complements of hyperplanes of \(X\)); as is well-known, change of charts is then given by rational and hence differentiable expressions. Similar constructions are known for other manifolds \(X\) such as Grassmannians, spaces of Lagrangians or conformal quadrics.

In the present work we will construct such manifolds in a very general context, in arbitrary dimension and over general base fields or \(-\)rings instead of \(\mathbb{R}\) or \(\mathbb{C}\). The present and first part contains the algebraic theory, and Part II ([BN03]) contains the analytic theory. For the case of base fields other than \(\mathbb{R}\) or \(\mathbb{C}\), we use in Part II suitable concepts of differential calculus and of smooth manifolds developed in [BGN03] which, in the case of locally convex real or complex
model spaces – in particular, for Banach and Fréchet spaces – agree with the usual concepts (but work more generally for manifolds modeled on any Hausdorff topological vector space). The present Part I is of independent interest since indeed a good deal of the above mentioned constructions is purely algebraic and admits a beautiful Lie- and Jordan theoretic interpretation. Geometrically, we work in the context of \textit{generalized projective geometries} (introduced in \cite{Be02}), and algebraically, in the context of \textit{3-graded Lie algebras} which in turn correspond to Jordan pairs (however, the paper is self-contained, and we assume only basic knowledge of Lie-algebras).

As in the ordinary projective case, it is a purely algebraic problem to define the chart domains, to give the precise description of the intersection of chart domains and and to find explicit formulas for the transition maps between different charts. Once this is established, differential calculus can be applied in order to show in Part II that these structures are differentiable under some suitable and natural assumptions. In this way we not only obtain e.g. Grassmannian manifolds, Lagrangian manifolds or conformal quadrics in arbitrary dimension over \( K = \mathbb{R}, \mathbb{C}, \mathbb{Q}, \ldots \), but also a wealth of symmetric spaces (over \( K \)) which generalize the symmetric Banach manifolds (see the monograph \cite{Up85}) but include many completely new examples that had not been accessible before. The symmetric spaces thus constructed are precisely those which are in the image of the \textit{Jordan-Lie functor} (cf. \cite{Be02}, \cite{Be00}).

Let us now describe the contents in some more detail. Our basic objects are on the one hand \textit{3-graded Lie algebras}, i.e. Lie algebras of the form \( \mathfrak{g} = \mathfrak{g}_1 \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_{-1} \) satisfying the relations \([\mathfrak{g}_0, \mathfrak{g}_1] \subset \mathfrak{g}_{+1}\) and on the other hand \textit{3-filtered Lie algebras}, i.e. Lie algebras \( \mathfrak{g} \) with a flag \( f : 0 = f_2 \subset f_1 \subset f_0 \subset \mathfrak{g} \) of subalgebras such that \([f_0, f_2] \subset f_{+1} \cap f_{-1} \subset \mathfrak{g} \). For simplicity we shall also write these flags as pairs \( f = (f_1, f_0) \). If \( \mathfrak{g} \) is 3-graded, then \( D(X) = iX \) \((X \in \mathfrak{g}_1)\) defines a derivation of \( \mathfrak{g} \) such that \( \mathfrak{d}^3 = D \), called the characteristic element, and if \( D \) is inner, \( D = \text{ad}(E) \), \( E \) will be called an Euler operator. The \textit{space of inner 3-gradings} of \( \mathfrak{g} \) is
\[
\mathcal{G} = \{ \text{ad}(E) : E \in \mathfrak{g}, \text{ad}(E)^3 = \text{ad}(E) \}.
\]
As usual in algebra, graded structures have underlying \textit{filtered structures}. However, for every 3-grading, there are \textit{two} naturally associated filtrations, \( f^+ := f^+(D) : \mathfrak{g}_1 \subset \mathfrak{g}_1 \oplus \mathfrak{g}_0 \subset \mathfrak{g} \) and \( f^- := f^-(D) = f^+(-D) : \mathfrak{g}_{-1} \subset \mathfrak{g}_{-1} \oplus \mathfrak{g}_0 \subset \mathfrak{g} \). If
\[
\mathcal{F} = \{ f^+(D) : D \in \mathcal{G} \}
\]
denotes the \textit{space of inner 3-filtrations of} \( \mathfrak{g} \), then we have an injection
\[
\mathcal{G} \hookrightarrow \mathcal{F} \times \mathcal{F}, \quad D \mapsto (f^+(D), f^-(D)).
\]
The spaces \( \mathcal{G} \) and \( \mathcal{F} \) carry many interesting geometric structures; one may say that the pair \((\mathcal{F} \times \mathcal{F}, \mathcal{G})\) is a “universal model of the generalized projective geometry associated to \( \mathfrak{g} \)”. On \( \mathcal{F} \times \mathcal{F} \) there is a natural relation of being transversal: two flags \( \mathfrak{e} = (e_1, e_0) \) and \( \mathfrak{f} = (f_1, f_0) \) are transversal if
\[
\mathfrak{g} = e_1 \oplus f_0 = f_1 \oplus e_0.
\]
Our key result on the structure of 3-graded Lie algebras (Theorem 1.6) affirms that \( \mathcal{G} \subset \mathcal{F} \times \mathcal{F} \) is exactly the set of pairs of transversal inner 3-filtrations of \( \mathfrak{g} \), and the set \( \mathcal{F} \) of filtrations transversal to a given filtration \( \mathfrak{f} \) carries canonically the structure of an affine space over \( K \) with translation group \( (f_1, +) \). The \textit{elementary projective group} \( \mathcal{G} = \mathcal{G}(D) \) of the 3-graded Lie algebra \( (\mathfrak{g}, D) \) is the group of automorphisms of \( \mathfrak{g} \) generated by the abelian groups \( U^\pm = e^{\text{ad}(x \pm 1)} \); it acts on \( \mathcal{F} \) and on \( \mathcal{G} \). We realize the \textit{projective completion} \((X^+, X^-)\) of the pair \((\mathfrak{g}_1, \mathfrak{g}_{-1})\) as the \( G \)-orbits in \( \mathcal{F} \) of the base points \( f^+ \) and \( f^- \) such that \( V^\pm := U^\pm . f^+ = (f^\pm)^+ \) are “affine parts of \( X^\pm \)” (Theorem 1.12). Summing up, the “generalized projective geometry \((X^+, X^-)\)” is imbedded as a subgeometry in \((\mathcal{F}, \mathcal{F})\).

Using this model, we have a natural definition of the “tangent bundle” \( T \mathcal{F} \) of \( \mathcal{F} \) and of a “structure bundle” \( T' \mathcal{F} \) (taking the role of a cotangent bundle), and of sections of these bundles. Thus we can define, in a purely algebraic context, \textit{vector fields} on \( \mathcal{F} \) as well as a certain operator between \( T' \mathcal{F} \) and \( T \mathcal{F} \) called the \textit{canonical kernel} (Chapter 2). Over the affine
parts $V^\pm$, the bundles and their sections can be trivialized, and it is seen that our vector fields are actually quadratic polynomial and that the canonical kernel coincides with the well-known Bergman operator from Jordan theory (see below). Thus we get a very natural interpretation of the “Koecher construction” which consists of realizing a 3-graded Lie algebra by quadratic polynomial vector fields (cf. also [Be00, Ch. VII], where in the finite-dimensional case another natural interpretation of this construction is given by using the integrability of almost (para-) complex structures). This approach naturally leads to one of the main results to be used in [BN03], namely the chart description of the action of $\text{Aut}(g)$ by “fractional quadratic maps” (Theorem 2.8).

In Chapter 3 we explain the link of the preceding results with Jordan theory: the pair $(V^+, V^-) = (g_1, g_{-1})$ together with the trilinear maps $T^\pm : V^\pm \times V^\mp \times V^\pm \to V^\pm$ given by triple Lie brackets is a (linear) Jordan pair, and one can express in a straightforward way all relevant formulas from the preceding chapter by these maps. Thus we obtain in a calculation-free way the Bergman-operator, the quasi-inverse and many of their fundamental relations and thus get new and “geometric” proofs of many Jordan theoretic results.

In Chapter 4 we add a new structure feature, namely an involution of the 3-graded Lie algebra. It leads to a bijection $p : X^+ \to X^-$ which is called a polarity in case that there exist non-isotropic points $x$ (i.e., $p(x) \cap x$). Then the space of all non-isotropic points carries the structure of symmetric space over $K$. We prove that the structure maps of this symmetric space are given by suitable Jordan-theoretic formulas (Theorem 4.4), which will allow to conclude in Part II of this work that these structure maps are differentiable and so we really deal with symmetric spaces in the category of smooth manifolds.

Chapters 5 up to 8 contain further material that is not strictly necessary for Part II of this work: in Chapter 5 we discuss those geometries that correspond to unital Jordan algebras: using our realization of $X^\pm$ as $G$-orbits in $\mathcal{F}$, they are characterized by the simple property that $V^+ \cap V^-$ is non-empty; in particular, $X^+ = X^-$. An axiomatic characterization of the “canonical identification of $X^+$ and $X^-$” has been given in [Be03]; thanks to our model, things are considerably easier here than in the axiomatic approach.

In Chapter 6 some functorial aspects of our constructions are investigated. It is shown that surjective homomorphisms of 3-graded Lie algebras induce equivariant maps of the associated geometries and we also show that inclusions of inner 3-graded subalgebras containing $\mathfrak{g}_1 + \mathfrak{g}_{-1}$ induce isomorphisms of the corresponding geometries.

In Chapter 7 we discuss central extensions of inner 3-graded Lie algebras. We show that for each central extension $\mathfrak{q} : \hat{\mathfrak{g}} \to \mathfrak{g}$ of an inner 3-graded Lie algebra $\mathfrak{g}$ the extended Lie algebra $\hat{\mathfrak{g}}$ carries a natural structure of an inner 3-graded Lie algebra for which $\mathfrak{q}$ is a morphism of 3-graded Lie algebras. We further construct a universal inner 3-graded central extension of $\mathfrak{g}$. We know from Chapter 6 that quotient maps induce maps on the level of geometries. For central extensions we show that these maps are isomorphisms.

In the final Chapter 8, we look at an important class of geometries, the Grassmannian geometries: let $R$ be an associative algebra over the commutative ring $K$, $V$ be a right $R$-module, $\mathcal{P}$ the space of all $R$-linear projectors $V \to V$ and $\mathcal{C}$ be the space of all $R$-submodules of $V$ that admit a complement. Then, by elementary linear algebra, the pair $(\mathcal{C} \times \mathcal{P})$ has the main features of a generalized projective geometry (Prop. 8.2, cf. also [Be01]), and in fact there is a homomorphism into the geometry $(\mathcal{F} \times \mathcal{G})$ with $\mathcal{G} = \mathfrak{gl}_R(V)$ which induces isomorphisms on subgeometries that are homogeneous under the elementary projective groups (Theorem 8.4). Such geometries, called Grassmannian geometries, correspond to special Jordan pairs, i.e., to subpairs of associative pairs. In particular, if $V = R$, then the Grassmannian geometry can also be called the “geometry of right ideals of the associative algebra $R$”; it corresponds to $R$, seen as a Jordan algebra over $K$.

Finally, we would like to add some comments on related work and on some open problems. The elementary projective group and the projective completion of a general Jordan pair have been introduced by J. Faulkner ([F83]), and results closely related to ours have been obtained by O. Loos ([L095]). Their results are based on the axiomatic theory of Jordan pairs ([L75]) and hence work even for base rings in which 2 or 3 are not invertible. In contrast, we work in a Lie
1. Three-graded and three-filtered Lie algebras

1.1. Three-graded Lie algebras. A 3-graded Lie algebra (over \( \mathbb{K} \)) is a Lie algebra over \( \mathbb{K} \) of the form \( \mathfrak{g} = \mathfrak{g}_1 \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_{-1} \) such that \( \mathfrak{g}_k \mathfrak{g}_{k+1} \subset \mathfrak{g}_{k+2} \), i.e., \( \mathfrak{g}_{\pm 1} \) are abelian subalgebras which are \( \mathfrak{g}_0 \)-modules, in the following often denoted by \( \mathfrak{V}_\pm \) or \( \mathfrak{g}_\pm \), and \( \mathfrak{g}_1, \mathfrak{g}_{-1} \subset \mathfrak{g}_0 \). The map \( D : \mathfrak{g} \to \mathfrak{g} \) defined by \( DX = iX \) for \( X \in \mathfrak{g} \) is a derivation of \( \mathfrak{g} \), called the characteristic element of the grading. It satisfies the relation \( (D - \text{id})D(D + \text{id}) = 0 \), i.e., \( D^3 = D \); we say that it is a tripotent derivation. Conversely, any tripotent derivation \( D : \mathfrak{g} \to \mathfrak{g} \) is diagonalizable with possible eigenvalues \( -1, 0, 1 \) and corresponding decomposition of \( X \in \mathfrak{g} \):

$$
X = X_1 + X_0 + X_{-1}, \quad X_0 = X - D^2 X, \quad X_1 = \frac{DX + D^2 X}{2}, \quad X_{-1} = -\frac{DX + D^2 X}{2}.
$$

(1.1)

Since \( D \) is a derivation, this eigenspace decomposition is a 3-grading. Therefore we may identify the space of 3-gradings of \( \mathfrak{g} \) with the set

$$
\mathcal{G} := \{ D \in \text{der}(\mathfrak{g}) : D^3 = D \}
$$

of tripotent derivations. If \( D = \text{ad}(E) \) is an inner tripotent derivation, then \( E \) is called an Euler operator, and we denote by

$$
\mathcal{G} := \{ \text{ad}(E) : E \in \mathfrak{g}, \text{ad}(E)^3 = \text{ad}(E) \}
$$

(1.2)

the space of inner 3-gradings of \( \mathfrak{g} \). The odd part of the 3-graded Lie algebra \( (\mathfrak{g}, D) \) is \( \mathfrak{g}_{-1} \oplus \mathfrak{g}_1 \), and we say that \( (\mathfrak{g}, D) \) is minimal if it is generated by its odd part, that is, \( \mathfrak{g}_0 \) is generated by the brackets \( [\mathfrak{g}_1, \mathfrak{g}_{-1}] \).
The following degenerate cases may arise: \( D^2 = \text{id} \), then \( \mathfrak{g} \) must be abelian, and we have merely a decomposition of a \( K \)-module into complementary subspaces; \( D^2 = D \), then \( \mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1 \) is nothing but a \( \mathfrak{g}_0 \)-module \( \mathfrak{g}_1 \), in particular, \( D = 0 \) corresponds to the case \( \mathfrak{g}_1 = \{0\} \).

1.2. The projective elementary group. Let \((\mathfrak{g}, D)\) be a 3-graded Lie algebra over \( K \). For \( x \in \mathfrak{g}_{\pm 1} \), the operator \( e^{adx} = 1 + adx + \frac{1}{2}(adx)^2 \) is a well defined automorphism of \( \mathfrak{g} \). (In order to check that \( e^{ad(x)} \) is an automorphism we need that \( \mathfrak{g} \) has no 3-torsion.) The group generated by these operators,

\[
G := G(D) := \text{PE}(\mathfrak{g}, D) := \langle e^{adx}, x \in \mathfrak{g}_{\pm 1} \rangle \subseteq \text{Aut}(\mathfrak{g}),
\]

is called the projective elementary group of \((\mathfrak{g}, D)\) (see Section 3.2 for the relation with the projective elementary group defined in Jordan theoretic terms, as in [Fa83], [Lo95]). Sometimes it will be useful to have a matrix notation for elements of \( G \): if \( g \in \text{Aut}(\mathfrak{g}) \), we let, with respect to the fixed 3-grading,

\[
g_{ij} := \text{pr}_i \circ g \circ i_j : \mathfrak{g}_j \to \mathfrak{g}_i, \quad i, j = 1, 0, -1,
\]

where \( i_j : \mathfrak{g}_j \to \mathfrak{g} \) are the inclusion maps and \( \text{pr}_i = \text{pr}_i(D) : \mathfrak{g} \to \mathfrak{g}_i \) the projections, given by

\[
\text{pr}_1 = \frac{D + D^2}{2}, \quad \text{pr}_0 = 1 - D^2, \quad \text{pr}_{-1} = \frac{D^2 - D}{2},
\]

and write \( g \) in “matrix form”

\[
g = \begin{pmatrix}
g_{11} & g_{10} & g_{1-1} 
g_{01} & g_{00} & g_{0-1} 
g_{-1, 1} & g_{-1, 0} & g_{-1, -1}
\end{pmatrix}.
\]

The subgroups \( U^\pm := U^\pm(D) := e^{adg_{\pm}} \) of \( G \) are abelian and generate \( G \). If the grading derivation is inner, \( D = \text{ad}(E) \), then

\[
\exp : \mathfrak{g}_{\pm 1} \to U^\pm, \quad X \mapsto e^{ad(X)}
\]

is injective since \( v \in \mathfrak{g}_{\pm} \) implies \( e^{adv}.E = E \mp v \). In the general case, we define the automorphism group of \((\mathfrak{g}, D)\) to be

\[
\text{Aut}(\mathfrak{g}, D) = \{ g \in \text{Aut}(\mathfrak{g}) : g \circ D = D \circ g \},
\]

and we further define subgroups \( H := H(D) \) and \( P^\pm := P^\pm(D) \) of \( G \) via

\[
H := G(D) \cap \text{Aut}(\mathfrak{g}, D) \quad \text{and} \quad P^\pm := HU^\pm = U^\pm H.
\]

(If \( D \) is inner, \( D = \text{ad}(E) \), then \( H = \{ h \in G : h \circ \text{ad}E \circ h^{-1} = \text{ad}E \} = \{ h \in G : h \cdot E = E \cdot h \} \). The groups \( U^\pm \) are abelian, and since the group \( H \) commutes with \( D \), it preserves the grading, hence normalizes \( U^\pm \), so that \( P^\pm \) are subgroups of \( G \). Using notation from Equation (1.4), the generators of \( G \) are represented by the following matrices (where \( x \in \mathfrak{g}_1, y \in \mathfrak{g}_{-1}, h \in H \):

\[
\begin{pmatrix}
1 & \text{ad}x & \frac{1}{2}\text{ad}(x)^2 \\
0 & 1 & \text{ad}x \\
0 & 0 & 1
\end{pmatrix}, \begin{pmatrix}
1 & 0 & 0 \\
0 & \text{ad}y & 1 \\
0 & \frac{1}{2}\text{ad}(y)^2 & \text{ad}y
\end{pmatrix}, h = \begin{pmatrix}
h_{11} & h_{00} & h_{-1, -1}
\end{pmatrix}.
\]

More information on the group \( G(D) \) for inner 3-gradings \( D \) is given in Theorem 1.12.

Sometimes it will be useful to replace \( G \) by a slightly bigger group: if \( D \in \mathcal{G} \) and \( r \in K^\times \), then, using the matrix notation (1.4),

\[
h^{(D, r)} := \begin{pmatrix} r & 1 \\
1 & r^{-1}
\end{pmatrix} = r \text{pr}_1 + \text{pr}_0 + r^{-1} \text{pr}_{-1},
\]

(16)
with the $pr_{i}$ as in Equation (1.3), defines an automorphism of $(g, D)$ normalizing $U^{\pm}$ and commuting with all elements of the group $\text{Aut}(g, D)$. The group $G_{\text{ext}}$ generated by $G$ and the group $\{ h^{(B, r)} : r \in \mathbb{K}^\times \}$ will be called the extended projective elementary group.

1.3. Three-filtered Lie algebras. A 3-filtered of a Lie algebra $g$ is a flag of subspaces

$$0 = f_{2} \subset f_{1} \subset f_{0} \subset f_{-1} = g$$

such that

$$[f_{k}, f_{l}] \subset f_{k+l}. \quad (1.7)$$

Supressing the trivial parts $f_{2}$ and $f_{-1}$ in the notation, we will denote such a flag by $\mathfrak{f} = (f_{1}, f_{0})$ or $\mathfrak{f} : (f_{1} \subset f_{0})$. Let $\mathcal{F}$ be the set of such flags $\mathfrak{f}$, called the space of 3-filtrations of $g$. Conditions (1.7) are equivalent to the following requirements:

- $f_{0}$ is a subalgebra, and $f_{1}$ is an abelian subalgebra of $g$,
- $f_{1}$ is an ideal in $f_{0}$, and $[g, f_{1}] \subset f_{0}$.

It follows that the operators $\text{ad}(X)$ with $X \in f_{1}$ are 3-step nilpotent and hence the automorphism $e^{\text{ad}(X)}$ of $g$ is well-defined. We denote by

$$U(\mathfrak{f}) := e^{\text{ad}(f_{1})} = \{ e^{\text{ad}(X)} | X \in f_{1} \} \subset \text{Aut}(g) \quad (1.8)$$

the corresponding abelian group. From (1.7) it follows that $U(\mathfrak{f})$ preserves the filtration $\mathfrak{f}$. The filtration $\mathfrak{f}$ is also stable under the action of the subalgebra $f_{0}$.

1.4. Relation between 3-gradings and 3-filfiltrations. To any 3-grading $g = g_{1} \oplus g_{0} \oplus g_{-1}$ of $g$ with characteristic derivation $D \in \mathcal{G}$ we may associate two 3-filtrations of $g$, called the associated plus- and minus-filtration, given by the two flags

$$f^{+}(D) := (g_{1}, g_{0} \oplus g_{1}), \quad f^{-}(D) := (g_{-1}, g_{0} \oplus g_{-1}). \quad (1.9)$$

Clearly, $f^{+}(D) = f^{-}(-D)$. We will say that a 3-filtration is inner if it is of the form $\mathfrak{f} = f^{+}(\text{ad}(E)) = f^{-}(\text{ad}(-E))$ for some Euler operator $E$, and the space of inner 3-filtrations will be denoted by

$$\mathcal{F} := \{ f^{+}(D) : D \in \mathcal{G} \}. \quad (1.10)$$

By these definitions, the maps $\mathcal{G} \to \mathcal{F}$, $D \mapsto f^{+}(D)$ are surjective, and the map

$$\mathcal{G} \to \mathcal{F} \times \mathcal{F}, \quad D \mapsto (f^{+}(D), f^{-}(D)) \quad (1.11)$$

is injective (since $g_{\pm 1}$ are recovered by the filtration and $g_{0} = (g_{0} \oplus g_{1}) \cap (g_{0} \oplus g_{-1})$).

1.5. Transversality. Two flags $\mathfrak{e} = (e_{1}, e_{0})$ and $\mathfrak{f} = (f_{1}, f_{0})$ as above are called transversal if

$$g = e_{1} \oplus f_{0} = f_{1} \oplus e_{0}.$$

It is clear by construction that the two filtrations $f^{+}(D)$ and $f^{-}(D)$ associated to a 3-grading $D$ of $g$ are transversal. We will prove that, conversely, any pair of transversal inner 3-filtrations arises in this way. If $\mathfrak{f} \in \mathcal{F}$, we will use the notation

$$f^{\top} := \{ \mathfrak{e} \in \mathcal{F} : \mathfrak{e} \parallel \mathfrak{f} \} \quad (1.12)$$

for the set of inner 3-filtrations that are transversal to $\mathfrak{f}$, and

$$(\mathcal{F} \times \mathcal{F})^{\top} = \{ (\mathfrak{e}, \mathfrak{f}) \in \mathcal{F} \times \mathcal{F} : \mathfrak{e} \parallel \mathfrak{f} \} \quad (1.13)$$

for the set of transversal pairs.
Theorem 1.6. (Structure Theorem for the space of 3-filtrations.) With the notation introduced above, the following holds for any Lie algebra \( \mathfrak{g} \) over \( \mathbb{K} \):

(1) The space of inner 3-gradings can be canonically identified with the space of transversal pairs of inner 3-filtrations:

\[
\mathcal{G} = (\mathcal{F} \times \mathcal{F})^T
\]

In other words, two inner 3-filtrations \( \mathfrak{e} \) and \( \mathfrak{f} \) are transversal if and only if there exists an Euler operator \( E \) such that \( \mathfrak{f} = \mathfrak{f}^\dagger (\text{ad}(E)) \) and \( \mathfrak{e} = \mathfrak{f}^\dagger (\text{ad}(E)) \).

(2) For any inner 3-filtration \( \mathfrak{f} \), the space \( \mathfrak{f}^\dagger \) carries a natural structure of an affine space over \( \mathbb{K} \) with translation group \((\mathfrak{f}_1,+\)\). The group \( \mathfrak{f}_1 \) acts simply transitively on \( \mathfrak{f}^\dagger \) by

\[
x \cdot \mathfrak{e} := e^{\text{ad}_x} \mathfrak{e}.
\]

Proof. (1) We have already remarked that \( \mathcal{G} \subset (\mathcal{F} \times \mathcal{F})^T \). In order to prove the other inclusion, let us assume that \((\mathfrak{e}, \mathfrak{f})\) is transversal. We have to show that \((\mathfrak{e}, \mathfrak{f}) \in \mathcal{G}\).

Since \( \mathfrak{f} \) is inner, there exists an Euler operator \( E \in \mathfrak{g} \) such that \( \mathfrak{f} = \mathfrak{f}^\dagger (\text{ad}(E)) \). We also choose a 3-grading

\[
\mathfrak{g} = \mathfrak{g}_1 \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_{-1} \quad \text{with} \quad \mathfrak{e}_1 = \mathfrak{g}_1, \quad \mathfrak{e}_0 = \mathfrak{g}_1 \oplus \mathfrak{g}_0.
\]

(1.14)

Let \( \text{pr}_j : \mathfrak{g} \rightarrow \mathfrak{g}_j, \ j = -1,0,1 \), denote the corresponding projections. Our assumption that \( \mathfrak{e} \) and \( \mathfrak{f} \) are transversal means that

\[
\mathfrak{g} = \mathfrak{e}_1 \oplus \mathfrak{f}_0 = \mathfrak{g}_1 \oplus \mathfrak{f}_0 \quad \text{and} \quad \mathfrak{g} = \mathfrak{f}_1 \oplus \mathfrak{e}_0 = \mathfrak{f}_1 \oplus (\mathfrak{g}_0 \oplus \mathfrak{g}_1).
\]

(1.15)

From (1.14) together with the fact that the restricted projection \( \text{pr}_{-1} : \mathfrak{f}_1 \rightarrow \mathfrak{g}_{-1} \) is surjective. Thus there exists a \( Z \in \mathfrak{f}_1 \) such that \( \text{pr}_{-1}(Z) = \text{pr}_{-1}(E) \), i.e. \( Z - E \in \ker \text{pr}_{-1} = \mathfrak{e}_0 \). Then \( [Z,E] = -Z \) leads to

\[
E' := e^{\text{ad}(Z)} E = E + [Z,E] = E - Z \in \mathfrak{e}_0.
\]

On the other hand, since \( Z \in \mathfrak{f}_1 \), the automorphism \( e^{\text{ad}(Z)} \) stabilizes the flag \( \mathfrak{f} \), and hence

\[
\mathfrak{f}^\dagger (\text{ad}(E')) = e^{\text{ad}(Z)} \mathfrak{f}^\dagger (\text{ad}(E)) = e^{\text{ad}(Z)} \mathfrak{f} = \mathfrak{f}.
\]

We may therefore, after replacing \( E \) by \( E' \), assume that \( E \in \mathfrak{e}_0 \). This implies that \( \mathfrak{f}_1 \) is invariant under \( \text{ad} E \), and since \( \text{ad} E \) acts by \( -\text{id} \) on the quotient space \( \mathfrak{g}/\mathfrak{f}_0 \cong \mathfrak{e}_1 \), it follows that \( [E,X] = -X \) for each \( X \in \mathfrak{e}_1 \), hence

\[
\mathfrak{e}_1 = \{ X \in \mathfrak{g} : [E,X] = -X \}.
\]

Further \( \mathfrak{e}_0 \oplus \mathfrak{f}_1 = \mathfrak{g} \), and \( \mathfrak{f}_1 \) is the 1-eigenspace of \( \text{ad} E \), so that the invariant subspace \( \mathfrak{e}_0 \) must be the sum of the 0- and -1-eigenspace of \( \text{ad} E \), and thus \( \mathfrak{e} = \mathfrak{f}^\dagger (\text{ad}(E)) \).

(2) Assume \( \mathfrak{e} \cap \mathfrak{f}_1 \) is the 1-eigenspace of \( \text{ad} E \), and \( \mathfrak{f}_1 \) is the 1-eigenspace of \( \text{ad} E \), so that the invariant subspace \( \mathfrak{e}_0 \) must be the sum of the 0- and -1-eigenspace of \( \text{ad} E \), and thus \( \mathfrak{e} = \mathfrak{f}^\dagger (\text{ad}(E)) \).

Let us prove that this action is transitive. We assume that \( \mathfrak{e} \cap \mathfrak{f}_1 \) and \( \mathfrak{e} \cap \mathfrak{f}_1 \). By Part (1), there exists an Euler operator \( E \) such that \( \mathfrak{f} = \mathfrak{f}^\dagger (\text{ad}(E)) \) and \( \mathfrak{e} = e^{\text{ad}(E)} \mathfrak{f} \). As in the proof of Part (1), we find \( Y \in \mathfrak{f}_1 \) such that

\[
E := e^{\text{ad}(Y)} E = E - Y \in \mathfrak{e}_0.
\]

Then the argument in (1) implies that \( \text{ad} E' \) is a characteristic element of the 3-grading

\[
\mathfrak{g}_1 := \mathfrak{f}_1, \quad \mathfrak{g}_0 := \mathfrak{f}_0 \cap \mathfrak{e}_0, \quad \mathfrak{g}_{-1} := \mathfrak{e}_1
\]

defined by the pair \((\mathfrak{f}, \mathfrak{e})\). Therefore

\[
\mathfrak{e} = \mathfrak{f}^\dagger (\text{ad}(E')) = e^{\text{ad} Y} \mathfrak{f}^\dagger (\text{ad}(E)) = e^{\text{ad} Y} \mathfrak{e}'.
\]
Hence $\epsilon'$ and $\epsilon$ are conjugate under the group $U(\mathfrak{s})$.

Finally, we prove that the action is simply transitive. Assume that $\epsilon \in \mathfrak{f}^\perp$ and $X \in \mathfrak{h}_1$ are such that $e^{ad(X)\epsilon} = \epsilon$. Then $e^{ad(X)}$ fixes the transversal pair $(\epsilon, \mathfrak{f})$ and hence commutes with $ad(E)$, where $E$ is an Euler operator such that $(\mathfrak{f}, \epsilon) = (\mathfrak{f}^+ (ad(E)), \mathfrak{f}^- (ad(E)))$. Applying this to the element $E \in \mathfrak{g}$, we get, since $[E, X] = -X$,

$$0 = e^{ad(X)} ad(E) = ad(E) \circ e^{ad(X)} \circ (E, E - X) = -X.$$

**Corollary 1.7.** Let $D_1 = ad(E_1), D_2 = ad(E_2) \in \mathcal{G}$ and $\mathfrak{g}_1 := \{ X \in \mathfrak{g} | [E_1, X] = X \}$. Then the following are equivalent:

1. $E_1$ and $E_2$ have the same associated $+\text{-filtration}$: $\mathfrak{f}^+ (ad(E_1)) = \mathfrak{f}^+ (ad(E_2))$.
2. $D_1 - D_2 \in ad(\mathfrak{g}_1)$.
3. $[D_1, D_2] = D_2 - D_1$.
4. There is $v \in \mathfrak{g}_1$ such that $D_2 = e^{ad\cdot D_1} e^{-ad\cdot v}$.

**Proof.** (4) implies (1) since $U(\mathfrak{f}^+ (D_1))$ preserves $\mathfrak{f}^+ (D_1)$. Conversely, if (1) holds, then $\mathfrak{f}^- (D_2)$ is transversal to $\mathfrak{f}^+ (D_2) = \mathfrak{f}^+ (D_1)$, and now (4) follows from Part (2) of Theorem 1.6.

From (4) it follows that $ad(E_2) = ad(E_1 + [v, E_1] + \frac{1}{2} [v, [v, E_1]]) = ad(E_1 - v)$, whence (2), and from this it follows that $[D_1, D_2] = ad([E_1, E_2]) = ad([E_1, -v]) = ad(v) = ad(E_1 - E_2)$, whence (3), and finally from (3) we get (4) by letting $v := E_1 - E_2$, which leads to $e^{ad\cdot D_1} E_1 = E_1 + [v, E_1] = E_1 + E_2 - E_1 = E_2$.

Next we state a "matrix version" of Part (1) of Theorem 1.6, using the matrix notation introduced in Equation (1.4).

**Corollary 1.8.** With respect to a fixed inner 3-grading given by the Euler operator $E$, with corresponding pair of 3-filtrations $(\mathfrak{f}^-, \mathfrak{f}^+)$ = $(\mathfrak{f}^+(D), \mathfrak{f}^+(D)) = ((\mathfrak{g}_{-1}, \mathfrak{g}_0, \mathfrak{g}_{-1}), (\mathfrak{g}_1, \mathfrak{g}_0 + \mathfrak{g}_1))$, the following statements are equivalent:

1. $(g, \mathfrak{f}^-, \mathfrak{f}^+) \in \mathcal{G}$.
2. $\mathfrak{f}^+$ and $g \mathfrak{f}^-$ are transversal.
3. $g_{-1, -1}$ and $(g^{-1})_{11}$ are invertible in $End(g_{-1})$, resp., in End(\mathfrak{g}_1).

**Proof.** The equivalence of (1) and (2) is given by Theorem 1.6(1). Now, (2) is equivalent to (4) and (5):

4. $(g_{-1})$ is a complement of $\mathfrak{g}_1 \oplus \mathfrak{g}_0$ and $g(g_{-1} \oplus \mathfrak{g}_0)$ is a complement of $\mathfrak{g}_1$,
5. $(g_{-1})$ is a complement of $\mathfrak{g}_1 \oplus \mathfrak{g}_0$ and $g^{-1}(\mathfrak{g}_1)$ is a complement of $\mathfrak{g}_{-1} \oplus \mathfrak{g}_0$,
and clearly (5) is equivalent to (3).

**Definition 1.9.** For $x \in \mathfrak{g}_1$ and $g \in Aut(\mathfrak{g})$, we define

$$d_g(x) := (e^{-ad(x)} g^{-1})_{11}, \quad c_g(x) := (g e^{ad(x)})_{-1, -1}.$$

Then

$$d_g^+ := d_g : \mathfrak{g}_1 \to End(\mathfrak{g}_1), \quad c_g^+ := c_g : \mathfrak{g}_1 \to End(\mathfrak{g}_{-1})$$

are quadratic polynomial maps, called the denominator and co-denominator of $g$ (w.r.t. the fixed inner grading defined by $ad(E)$). In a similar way, $d_g^-$ and $c_g^-$ are defined.

Writing $g$ and $e^{ad(x)}$ in matrix form (1.4), the denominator for $g^{-1}$ is given by

$$d_{g^{-1}}(x) = g_{11} - ad(x) \circ g_{10} + \frac{1}{2} ad(x)^2 \circ g_{11, 11},$$

and similarly for the co-denominator. For the generators of $G$ we get the following (co-) denominators (where $v \in \mathfrak{g}_1$, $w \in \mathfrak{g}_{-1}$):

$$g = e^{ad(v)} : \quad d_g(x) = id_{\mathfrak{g}_1}, \quad c_g(x) = id_{\mathfrak{g}_{-1}}$$

$$g = e^{ad(w)} : \quad d_g(x) = id_{\mathfrak{g}_1} + ad(x) ad(w) + \frac{1}{4} ad(x)^2 ad(w)^2,$$

$$c_g(x) = id_{\mathfrak{g}_{-1}} + ad(w) ad(x) + \frac{1}{4} ad(w)^2 ad(x)^2 \quad (1.16)$$

$$g = h \in H : \quad d_h(x) = (h_{11})^{-1} = (h^{-1})_{11}, \quad c_h(x) = h_{-1, -1}.$$
For $g = e^{ad(w)}$ as in the second equation, we introduce the notation

$$B_+(x, w) := d_g(x), \quad B_-(w, x) := e_g(x). \quad (1.17)$$

These linear maps define the Bergman operator, see Section 3.3.

**Corollary 1.10.** With respect to a fixed inner 3-grading given by the Euler operator $E$, we identify $V^+ := \mathfrak{g}_1$ with the set $(f^+)^* = e^{ad(V^+)}f^+$. Then for $x \in V^+$ the following statements are equivalent:

1. $(g, x, f^+)$ ∈ $\mathcal{G}$.
2. $f^+$ and $g.x$ are transversal, i.e., $g.x$ ∈ $V^+$.
3. $e_g(x)$ and $d_g(x)$ are invertible in $\text{End}(\mathfrak{g}_{-1})$, resp., in $\text{End}(\mathfrak{g}_1)$.

**Proof.** This follows by applying Corollary 1.8 to the element $g^{ad(x)} \in \text{Aut}(\mathfrak{g})$.

In particular, for $g = e^{ad(w)}$ with $w \in \mathfrak{g}_{-1}$, it follows that $g.x \in V^+$ if and only if $B_+(x, w)$ and $B_-(w, x)$ are invertible.

### 1.11. The projective geometry of a 3-graded Lie algebra.

Recall from Section 1.2 the definition of the projective elementary group $G := G(D)$. Using Theorem 1.6(1), we may identify an inner grading $D = ad(E)$ with the corresponding pair $(f, \epsilon) = (f^+(D), f^+(D))$ of inner filtrations; hence we may also write $G(f, \epsilon)$ for the elementary group $G(D)$, and similarly for $H(D)$ and $P^\pm(D)$. If $f, \epsilon, \epsilon'$ are inner 3-filtrations such that $\epsilon^\top f$ and $\epsilon'^\top f$, then Theorem 1.6(2) implies that $\epsilon$ and $\epsilon'$ are conjugate under $G(f, \epsilon)$, and hence we have $G(f, \epsilon) = G(f, \epsilon')$. Therefore we may define the *projective elementary group* of the inner 3-filtration $f$ to be $G(f) := G(f, \epsilon)$, where $\epsilon \in \mathcal{F}$ is any filtration that is transversal to $f$. Note that

$$U^+(f, \epsilon) = U^+(f)$$

is the abelian group defined by Eqn. (1.8) and hence is independent of $\epsilon$, whereas the groups $U^- = U^-(f, \epsilon)$, $H = H(f, \epsilon)$ and $P^- = P^-(f, \epsilon)$ depend on the choice of $\epsilon$. (We will see below that $P^+$ does not depend on $\epsilon$.) We define the following homogeneous spaces:

$$X^\pm := G/P^\mp, \quad M := G/H. \quad (1.18)$$

For reasons that will be explained below, the data $(X^+, X^-, M)$ are called the *(generalized)* projective geometry associated to the graded Lie algebra $(\mathfrak{g}, D)$. The base point $(P^-, P^+)$ in $X^+ \times X^-$ will often be denoted by $(o^-, o^+)$. 

**Theorem 1.12.** (Structure theorem for the projective geometry of a 3-graded Lie algebra)

With the notation introduced above, the following holds:

1. The orbits of $D := ad(E) \in \mathcal{G}$, resp., of $f^+ \in \mathcal{F}$, under the action of $G$ are isomorphic to $M$, resp., to $X^\pm$. In other words,

   $$H = \{ g \in G(D) : g.(f^+, f^+) = (f^-, f^+) \} \quad \text{and} \quad P^\pm = \{ g \in G(D) : g.f^+ = f^\pm \}.$$

   Moreover, $P^+ \cap P^- = H$, $P^\pm \cap U^\pm = \{1\}$ and

   $$P^\pm = \{ g \in G : gDg^{-1} - D \in \text{ad}(\mathfrak{g}_{\pm1}) \} = \{ g \in G : g.E - E \in \mathfrak{z}(\mathfrak{g}) + \mathfrak{g}_{\pm1} \}.$$

2. If we identify $X^\pm$ with the corresponding orbits in $\mathcal{F}$, then

   $$G \cap (X^+ \times X^-) = M.$$

3. For every element $\epsilon \in X^-$, the set $\epsilon^\top$ is contained in $X^+$ and carries a well-defined structure of an affine space over $\mathbb{K}$ with translation group $\epsilon_1 = \mathfrak{g}_1$. In particular, $(o^-)^\top$ is canonically identified with $V^+ = e^{ad(\mathfrak{g}_1)}o^+$. 

Consider the set \( \Omega^+ \) of elements of \( G \) sending the base point \( o^+ \in X^+ \) to a point of the affine part \( V^+ \subset X^+ \),

\[
\Omega^+ := \{ g \in G : g.o^+ \in V^+ \}.
\]

Then the map

\[
g_1 \times H \times g_{-1} \rightarrow \Omega^+, \quad (v, h, w) \mapsto e^{ad(v)}he^{ad(w)}
\]

is a bijection, and moreover

\[
\Omega^+ = \{ g \in G : d_g(o^+) \in GL(g_1), c_g(o^+) \in GL(g_{-1}) \}.
\]

The spaces \( X^+ \subset \mathcal{F} \) and \( M \subset \mathcal{G} \) are stable under the action of the automorphism group \( \text{Aut}(g, D) \) and of the extended projective elementary group \( G^\text{ext} \).

**Proof.**

(1) An element \( g \in G \) stabilizes \((\mathcal{F}, \mathcal{F}^-)\) if and only if it commutes with \( D = \text{ad}(E) \) which means that it belongs to \( H \).

It is clear that \( P^+ \) stabilizes \( \mathcal{F}^+ \). Conversely, assume that \( g \in G \) satisfies \( g.\mathcal{F}^+ = \mathcal{F}^+ \). Then \( g.\mathcal{F}^+ = \mathcal{F}^+ \) is transversal to \( \mathcal{F}^- \), and hence by Theorem 1.6(2) there exists \( v \in g_1 \) such that \( g.\mathcal{F}^- = e^{ad(v)}\mathcal{F}^- \). Then \( h := e^{-ad(v)}g \) preserves \((\mathcal{F}^+, \mathcal{F}^-)\) and thus belongs to \( H \). Therefore \( g = e^{ad(v)}h \) belongs to \( P^+ \). Hence \( P^+ \) is the stabilizer of \( \mathcal{F}^+ \). Similarly for \( P^- \).

It follows that \( P^+ \cap P^- \) is the stabilizer of \((\mathcal{F}^+, \mathcal{F}^-)\) which is \( H \). Next, assume \( g \in P^+ \cap P^- \).

Write \( g = e^{ad(v)} \) with \( v \in g_1 \). Since \( v \mapsto e^{ad(v)} \mathcal{F}^+ \) is injective (Theorem 1.6(2)), it follows from \( g.\mathcal{F}^+ = \mathcal{F}^+ \) that \( v = 0 \) and hence \( g = 1 \).

Finally, \( g \) stabilizes \( \mathcal{F}^+ \) if and only if \( D \) and \( gDg^{-1} \) have the same associated +,filtration, if and only if \( D^2 \) belongs to \( \text{ad}(g_1) \) (Corollary 1.7), whence the last claim of Part (1) for \( P^+ \), and similarly for \( P^- \).

(2) It is clear that the \( G \)-orbit \( G.(\mathcal{F}^+, \mathcal{F}^-) \) belongs both to \( X^+ \times X^- \) and to \( \mathcal{G} \). In order to prove the converse, let \((f, \epsilon) \in (X^+ \times X^-) \cap \mathcal{G} \). We may write \( f = g.\mathcal{F}^+ \) for some \( g \in G \). Then \( g^{-1}(f, \epsilon) = (\mathcal{F}^+, g^{-1} \mathcal{F}^-) \) again belongs to \((X^+ \times X^-) \cap \mathcal{G} \). According to Theorem 1.6, there exists \( v \in g_1 \) such that \( g^{-1} \epsilon = e^{ad(v)} \mathcal{F}^- \). It follows that \((f, \epsilon) = g.e^{ad(v)}(\mathcal{F}^+, \mathcal{F}^-) \) belongs to the \( G \)-orbit \( G.(\mathcal{F}^+, \mathcal{F}^-) \).

(3) As in the proof of (2), we translate by an element \( g \in G \) such that \( g.e = \mathcal{F}^- \), and then the claim is precisely the one of Part (2) of Theorem 1.6.

(4) Assume \( g \in \Omega^+ \) and let \( v := g.o^+ \in V^+ \). Then \( e^{-ad(v)}g.o^+ = o^+ \), and according to Part (1), it follows that \( p := e^{-ad(v)}g \in P^- \), whence the decomposition \( g = e^{ad(v)}p = e^{ad(v)}he^{ad(v)} \). Uniqueness follows from the fact that \( P^+ \cap P^- = H \). Also, it is clear that any element \( g \in U^+P^- \) belongs to \( \Omega^+ \).

The second claim is a reformulation of Corollary 1.10.

(5) Assume \( h \in \text{Aut}(g, D) \). From the relation \( h e^{ad(o)}h^{-1} = e^{ad(o)} h e^{ad(o)} \) it follows that \( h \) normalizes \( G \). Since \( h \) stabilizes \( \mathcal{F}^+ \), it follows that, for all \( g \in G \), \( h g \mathcal{F}^- = h g \mathcal{F}^- \mathcal{F}^- \mathcal{F}^- \) \( G.\mathcal{F}^- = X^+ \). It follows that \( X^+, X^- \) and \( M \) are stable under \( h \). Since \( G^\text{ext} \) is generated by \( G \) and all \( h^{(D, \epsilon)} \) (cf. Eqn. (1.6)), stability under \( G^\text{ext} \) also follows. \( \blacksquare \)

Since \( P^+ \cap P^- = H \),

\[
M \rightarrow X^+ \times X^-, \quad gH \mapsto (gP^-, gP^-)
\]

is a well-defined imbedding, and the following diagram commutes:

\[
\begin{array}{ccc}
G/H & \rightarrow & G/P^- \times G/P^+ \\
\downarrow & & \downarrow \\
\mathcal{G} & \rightarrow & \mathcal{F} \times \mathcal{F}
\end{array}
\]

Thus we may say that the data \((X^+, X^-, M)\) forms a subspace of \((\mathcal{F}, \mathcal{F}, \mathcal{G})\) on which the elementary projective group \( G \) acts transitively.

**1.13. The structure maps of the projective geometry.** Assume \((f_1, f_2, f_3)\) is a \( \text{"} \)generic triple\( \) of inner 3-filtrations; by this we mean that it belongs to the space

\[
(\mathcal{F} \times \mathcal{F} \times \mathcal{F})^\top := \{ (f_1, f_2, f_3) \in \mathcal{F} \times \mathcal{F} \times \mathcal{F} : f_1 \top f_2, f_3 \top f_2 \}.
\]

(1.21)
Since \( f_1 \) carries a natural structure of an affine space over \( K \) (Theorem 1.6(2)), we may take \( f_1 \) as origin in \( f_2 \), i.e., we turn \( f_2 \) into a \( K \)-module with zero vector \( f_1 \). Let \( r \in K \) and \( r f_3 \) be the ordinary multiple of \( f_3 \) in this \( K \)-module. Since it depends on \( f_1 \) and on \( f_2 \), we write

\[
\mu_r(f_1, f_2, f_3) := r_{1, f_3}(f_3) := r f_3 = (1 - r)f_1 + rf_3,
\]

where the latter expression only refers to the affine structure. The map

\[
\mu_r : (F \times F \times F)^T \to F, \quad (f_1, f_2, f_3) \mapsto \mu_r(f_1, f_2, f_3)
\]

(1.22)

is called the structure map of the projective geometry \( (F, F, G) \). By restriction to the subgeometry \( (X^+, X^-, M) \), we get in a similar way two structure maps

\[
\mu^{\pm} : (X^+ \times X^\mp \times X^\pm)^T \to X^\pm
\]

because for \( f_2 \in X^\mp \) we have \( f_2 \subseteq X^\pm \) by Theorem 1.12(3). In [Be02, Th. 10.1] it is shown that these maps satisfy two remarkable identities (PG1) and (PG2) which axiomatically define the category of generalized projective geometries. If \( r \in K^X \), then we have

\[
\mu_r(f_1, f_2, f_3) = h^{(D, r)} \cdot f_3,
\]

(1.23)

where \( h^{(D, r)} \) is the automorphism defined by Equation (1.6) and \( D \) corresponds to the 3-grading defined by the translational pair \( (f_1, f_2) \). The case \( r = -1 \) is of particular interest since it leads to associated symmetric spaces, see Chapter 4.

2. Tangent bundle, structure bundle and the canonical kernel

2.1. Tangent bundle and structure bundle. We continue to use the notation \( G, \) resp. \( F, \) for the space of inner 3-gradings (resp. 3-filtrations) of a Lie algebra \( g \). For a 3-filtration \( f = (f_1, f_0) \), we define \( K \)-modules by

\[
T_f F := g/f_0, \quad T'_f F := f_1,
\]

(2.1)

called the tangent space of \( F \) at \( f \), resp., the structural space of \( F \) at \( f \). If \( f = f^- (ad(E)) \) is the minus-filtration w.r.t. the Euler operator \( E \), then \( f_0 = g_0 \oplus g_{-1} \), and hence

\[
T_0 F \cong g_1, \quad T'_0 F = g_{-1}.
\]

It is not misleading to think of \( T'_f F \) as a sort of "cotangent space" of \( F \) at \( f \). We let

\[
T F := \bigcup_{f \in F} T_f F, \quad T'_F := \bigcup_{f \in F} T'_f F
\]

(2.2)

(disjoint union), called the tangent bundle of \( F \), resp., the structure bundle of \( F \). The group \( \text{Aut}(g) \) acts on \( G \) and on \( F \), and for any \( g \in \text{Aut}(G) \), the following maps are well-defined and linear:

\[
T_{fg} : T_f F \to T_{g f} F, \quad T'_{fg} : T'_f F \to T'_{g f} F, \quad Y \mod f_0 \to g Y \mod g f_0,
\]

(2.3)

and if we define now \( T_g : T F \to T F, \) \( T'_g : T'_F \to T'_F \) in the obvious way, then clearly the functorial properties \( T(g \circ h) = T(g) \circ T(h) \), and \( T'(g \circ h) = T'(g) \circ T'(h) \) hold. Finally, if a base point \( D \in G \) is fixed and \( X^\pm \subset F \) are as in Cor. 1.10, then the tangent spaces \( T_f X^\pm \), \( T'_f X^\pm \) and the corresponding bundles \( T X^\pm, T' X^\pm \) are defined. The natural group acting on these spaces is the normalizer of \( G(D) \) in \( \text{Aut}(g) \).
2.2. Vector fields and the canonical kernel. If \( Y \in \mathfrak{g} \) and \( \mathfrak{f} \in \mathcal{F} \) as is above, we say that

\[
Y_\mathfrak{f} := Y \mod \mathfrak{f}_0 \in T_\mathfrak{f} \mathcal{F}
\]

is the value of \( Y \) at \( \mathfrak{f} \), and the assignment \( Y : \mathcal{F} \to T \mathcal{F}, \mathfrak{f} \mapsto Y_\mathfrak{f} \) defines a vector field on \( \mathcal{F} \). The space of vector fields on \( \mathcal{F} \) is denoted by \( \mathfrak{X}(\mathcal{F}) \); it is a \( \mathbb{K} \)-module in the obvious way such that the surjection

\[
\mathfrak{g} \to \mathfrak{X}(\mathcal{F}), \quad Y \mapsto \overline{Y}
\]

becomes a \( \mathbb{K} \)-linear map which is equivariant w.r.t. the natural actions of \( \text{Aut}(\mathfrak{g}) \) on both spaces. In particular, the structural spaces \( T^*_\mathfrak{g} \mathcal{F} \) are subspaces of \( \mathfrak{g} \) and hence give rise to vector fields. Composing with evaluation at another point, we are lead to define, for \( (\mathfrak{f}, \mathfrak{e}) \in \mathcal{F} \times \mathcal{F} \), a \( \mathbb{K} \)-linear map by

\[
K_{\mathfrak{f}, \mathfrak{e}} : T^*_\mathfrak{f} \mathcal{F} = \mathfrak{e}_1 \to T^*_{\mathfrak{f}} \mathcal{F} = \mathfrak{g}/\mathfrak{f}_0, \quad Y \mapsto Y_\mathfrak{f} = Y \mod \mathfrak{f}_0.
\]

The collection of maps \( (K_{\mathfrak{f}, \mathfrak{e}}, K_{\mathfrak{e}, \mathfrak{f}}), (\mathfrak{f}, \mathfrak{e}) \in \mathcal{F} \times \mathcal{F} \), is called the canonical kernel. Note that \( K_{\mathfrak{f}, \mathfrak{e}} \) is bijective if and only if \( \mathfrak{e}_1 \) is a \( \mathbb{K} \)-module complement of \( \mathfrak{f}_0 \) in \( \mathfrak{g} \). In particular, if \( \mathfrak{f} = \mathfrak{f}^-(\text{ad}(E)) \), \( \mathfrak{e} = \mathfrak{f}^+ \text{(ad}(E)) \), then \( K_{\mathfrak{f}, \mathfrak{e}} \) is identified with a linear map \( \mathfrak{g}_1 \to \mathfrak{g}_1 \) which is simply the identity.

**Theorem 2.3.** For \( \mathfrak{f}, \mathfrak{e} \in \mathcal{F} \) the following statements are equivalent:

1. \( (\mathfrak{f}, \mathfrak{e}) \in \mathcal{G} \),
2. \( K_{\mathfrak{f}, \mathfrak{e}} : T^*_\mathfrak{f} \mathcal{F} \to T^*_\mathfrak{e} \mathcal{F} \) and \( K_{\mathfrak{e}, \mathfrak{f}} : T^*_\mathfrak{e} \mathcal{F} \to T^*_\mathfrak{f} \mathcal{F} \) are bijective.

**Proof.** The second condition clearly is equivalent to saying that \( \mathfrak{f} \) and \( \mathfrak{e} \) are transversal, and therefore Theorem 2.3 is a restatement of Part (1) of Theorem 1.6. ■

2.4. Trivialization over affine parts, and quadratic polynomial vector fields. In the following we will often fix an Euler operator \( E \), the associated 3-grading of \( \mathfrak{g} \) and the associated pair \( (\mathfrak{f}^-, \mathfrak{f}^+) = (\mathfrak{f}^-(\text{ad}(E)), \mathfrak{f}^+(\text{ad}(E))) \) of filtrations. The pair \( (\mathfrak{f}^-, \mathfrak{f}^+) \) then serves as a base point in \( \mathcal{G} \) and in the homogeneous space \( \mathcal{G} (\mathfrak{f}^-, \mathfrak{f}^+) \cong \mathcal{G} / \mathcal{H} \subset X^+ \times X^- \) (cf. Th. 1.12) and will also often be denoted by \( (\alpha^+, \alpha^-) \). The spaces \( V^\pm := \mathfrak{g}^{\pm1} \) are imbedded into \( X^\pm := \mathcal{G} \otimes \mathbb{F} \cong \mathcal{G} / \mathcal{P}^\pm \) via \( X \to \alpha^\text{ad}(X)^{\pm1} \); this imbedding will be considered as an inclusion, so that, for \( x \in X^+ \), the condition \( x \in V^+ \) means that \( (x, \alpha^-) \in \mathcal{G} \).

The reader may think of \( X^\pm \) as a kind of “manifolds” modeled on the \( \mathbb{K} \)-modules \( V^\pm \); we will say that

\[
A := \{ (g(V^+), g) : g \in \mathcal{G} \}, \quad \varphi_g : g(V^+) \to V^+, \quad gx \mapsto x
\]

is the natural atlas of \( X^+ \). Having this in mind, a natural question is to describe the structures introduced so far by a “trivialized picture” in the charts of the atlas \( A \). Since the spaces \( X^\pm \) are homogeneous under \( \mathcal{G} \), one can describe \( TX^\pm \) and \( T^*X^\pm \) as associated bundles: if \( \pi : P^\pm \to GL(W) \) is a homomorphism of \( P^\pm \) into the linear group of a \( \mathbb{K} \)-module \( W \), let

\[
G \times_{P^\pm} W \equiv G \times W / \sim
\]

with \( (g, w) \sim (g p, \pi(p)^{-1} w) \) for \( p \in P^\pm \). If \( \pi \) is the natural representation of \( P^- \) on \( W := \mathfrak{g}/(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1}) \equiv \mathfrak{g}_1 \) given by

\[
\pi(p) := p_{11} : \mathfrak{g}_1 \to \mathfrak{g}_1, \quad X \mapsto p_{1}(pX)
\]

(this is the action of \( P^- \) on \( T^+X^+ \)), then

\[
G \times_{p^-} \mathfrak{g}_1 \to TX^+, \quad [g, X] \mapsto (T_{\alpha^-} g)(X)
\]

is a \( G \)-equivariant bijection. Similarly, if \( \pi \) is the natural representation of \( P^- \) on \( W := \mathfrak{g}^{-1} \) given simply by \( \pi(p)X = pX = p_{-1,-1}X \), then

\[
G \times_{p^-} \mathfrak{g}_1 \to T^*X^+, \quad [g, X] \mapsto gX
\]
is a $G$-equivariant bijection. For $TX^-$ and $T'X^-$ we have similar formulas. If $f : G \to W$ is a function such that $f(gp) = \pi(p)^{-1}.f(g)$ for all $g \in G$ and $p \in P^-$, then via

$$s_f(gP^-) = [g, f(g)].$$

we get a well defined section of the natural projection $G \times_{P^=} W \to G/P^-$, and every section arises in this way. For instance, for $Y \in \mathfrak{g}$, the corresponding vector field $\tilde{Y}$ on $X^+$ is given by the function

$$\tilde{Y}_G : G \to \mathfrak{g}_1, \quad g \mapsto g^{-1}Y \bmod(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1}) = pr_1(g^{-1}Y),$$

(2.10)

where for the last equality we identified $\mathfrak{g}/(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1})$ and $\mathfrak{g}_1$. In fact, considering (2.8) as an identification, we have

$$\tilde{Y}_{\mathfrak{g},o+} = Y \bmod(g(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1})) = g(g^{-1}Y \bmod(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1})) = [g, g^{-1}Y \bmod(\mathfrak{g}_0 \oplus \mathfrak{g}^{-1})] = [g, \tilde{Y}_G(g)].$$

We consider the special case $g = e^{ad(v)}$ with $v \in \mathfrak{g}_1$. We identify the restriction of $\tilde{Y}$ to $V^+ \subset X^+$ with the map

$$\tilde{Y}^+ : V^+ \to V^+, \quad v \mapsto pr_1(e^{-ad(v)}Y) = pr_1(Y - [v, Y] + \frac{1}{2}[v, [v, Y]]) .$$

(2.11)

Note that the map $\tilde{Y}^+$ is a quadratic map from $V^+$ to $V^+$. In particular, it immediately follows from this formula that for $Y \in \mathfrak{g}_1$ this map is constant, for $Y \in \mathfrak{g}_0$ it is linear and for $Y \in \mathfrak{g}^{-1}$ it is homogeneous quadratic:

$$\tilde{Y}^+(v) = \begin{cases} Y & \text{for } Y \in \mathfrak{g}_1, \\ [Y, v] & \text{for } Y \in \mathfrak{g}_0, \\ \frac{1}{2}[v, [v, Y]] & \text{for } Y \in \mathfrak{g}^{-1}. \end{cases}$$

(2.12)

Similarly, $Y \in \mathfrak{g}$ gives rise to a quadratic map $\tilde{Y}^- : V^- \to V^-$. Summing up, associating to $Y \in \mathfrak{g}$ the quadratic polynomial map $\tilde{Y}^+ \times \tilde{Y}^- : V^+ \times V^- \to V^+ \times V^-$ gives rise to a trivialization map

$$\mathfrak{g} \to Pol_2(V^+, V^+) \times Pol_2(V^-, V^-)$$

where $Pol_2(W, W)$ is space of polynomial selfmappings of degree at most two of a $K$-module $w$. Elements of $\mathfrak{g}_0$ are mapped onto linear polynomials; in particular, the Euler operator $E$ is mapped onto $(id_{V^+} - id_{V^-})$. The following result will not be used in the sequel, but is recorded here for the sake of completeness.

**Proposition 2.5.** The trivialization map is a homomorphism of Lie algebras if we define the bracket of two quadratic polynomial maps $p, q : W \to W$ on a $K$-module $W$ by

$$[p, q](x) = dp(x)q(x) - dq(x)p(x)$$

where the (algebraic) differentials $dp(x), dq(x)$ of a (quadratic) polynomial mapping are defined in the usual way.

**Proof.** The commutator relations are directly checked by choosing $p, q$ in the homogeneous parts $\mathfrak{g}_1, \mathfrak{g}_0, \mathfrak{g}^{-1}$ of $\mathfrak{g}$.

For the corresponding result on the group level, recall from Definition 1.9 the nominator and co-denominator of an element $g \in G$.

**Proposition 2.6.** If $g \in \text{Aut}(\mathfrak{g})$ and $x \in V^+ \subset X^+$ are such that $d_g(x)$ and $c_g(x)$ are invertible (equivalently, if $g.x \in V^+$), then for all $Y \in \mathfrak{g}$,

$$\left(\overline{g^{-1}Y}^+\right)(x) = d_g(x)\tilde{Y}^+(g.x).$$
In particular, for $Y = v \in g_1$ we have

$$(g^{-1}v)^+ (x) = d_g(x)v.$$  

If $x, g_1x$ and $g_1g_2x$ belong to $V^+$, then the cocycle relation

$$d_{g_1g_2}(x) = d_{g_2}(x) \circ d_{g_1}(g_2x)$$

holds.

**Proof.** The assumption that $g \cdot x \in V^+$ means that $g \circ e^{\text{ad}(x)}$ belongs to the set $\Omega^+ \subset G$ defined in Theorem 1.12, Part (4). Therefore, according to this theorem, there exists a unique element $p(g, x) \in P^-$ such that $ge^{\text{ad}(x)} = e^{\text{ad}(g_1x)}p(g, x)$ and hence $p(g, x) = e^{-\text{ad}(g_2x)}ge^{\text{ad}(x)}$. From this we get

$$(p(g, x)^{-1})_{11} = (e^{-\text{ad}(x)}g^{-1}_1e^{\text{ad}(g_1x)})_{11} = pr_1 \circ \text{pr}_2 \circ (e^{-\text{ad}(g_2x)}g^{-1}_1e^{\text{ad}(x)} \circ \text{pr}_2)$$

This will be used in the last line of the following calculation (cf. also [Be00, VIII.B.2] for the general framework):

$$\begin{align*}
(g^{-1}Y)^+ (x) &= \tilde{Y}_G(e^{\text{ad}(x)}) = \tilde{Y}_G(e^{\text{ad}(g_1x)}p(g, x)) \\
&= \pi(p(g, x)^{-1})\tilde{Y}_G(e^{\text{ad}(g_2x)}) = (p(g, x)^{-1})_{11}\tilde{Y}_G(e^{\text{ad}(g_2x)}) = d_g(x)\tilde{Y}^+(g, x).
\end{align*}$$

The second assertion follows since $\tilde{v}^+$ is a constant vector field on $V^+$, see Equation (2.12). The cocycle relation now follows:

$$d_{g_1g_2}(x)v = (g^{-1}_1g^{-1}_2v)^+ (x) = d_{g_2}(x)(g^{-1}_1v)^+ (g_2x) = d_{g_2}(x) \circ d_{g_1}(g_2x)v.$$  

Proposition 2.6 implies in particular that the action of $g$ on the tangent bundle $TX^+$ is given in the canonical trivialization on $V^+$ by the expression $T_x g \cdot v = d_g(x)^{-1}v$; in Part II of this work we will show that, in presence of a differentiable structure, this really corresponds to the differential $dg(x)$ of $g$ at $x$, applied to $v$. – Similarly as in the proof of Prop. 2.6, it is seen that the action of $g$ on $T^*X^+$ is, in the trivialization $T^*(V^+) \cong V^+ \times V^-$ over the affine part $V^+ \subset X^+$, given by

$$T^*_x g : w = c_g(x)w,$$

and that the co-denominators also satisfy a cocycle relation $c_{g_1g_2}(x) = c_{g_1}(g_2x) \circ c_g(x)$.

### 2.7. Nominators

We apply the preceding proposition in the case where $Y$ is an Euler operator $E$ inducing the fixed 3-graded of $g$: for $g \in \text{Aut}(g)$ consider the vector field $g^{-1}E$ on $X^+$ and define the nominator of $g$ to be the quadratic polynomial map

$$n_g : V^+ \rightarrow V^+, \quad x \mapsto \tilde{g^{-1}}E^+ (x) = \text{pr}_1(e^{-\text{ad}(x)}g^{-1}E) = (e^{-\text{ad}(g_2x)}g^{-1}E)_{10}.$$

Using the matrix notation (1.4), we can also write

$$n_{g^{-1}}(x) = (g_{10} - \text{ad}(x) \circ g_{00} + \frac{1}{2} \text{ad}(x)^2 \circ g_{-10})(E).$$

For the generators of $G$ we get the following nominators: if $v \in g_1, w \in g_{-1}, h \in H$,

$$n_g(x) = \begin{cases} 
  x + v & \text{for } g = e^{\text{ad}[v]} \\
  x - \frac{1}{2} \text{ad}(x)^2 w & \text{for } g = e^{\text{ad}[w]} \\
  x & \text{for } g = h
\end{cases}$$

Note that the nominators will not depend on the Euler operator $E$ such that $\text{ad}(E) = D$ as long as $g$ acts trivially on the center of $g$; this is the case for all elements $g \in G$. For general $g \in \text{Aut}(g)$ such that $g \cdot x \in V^+$, we can apply the preceding proposition and get, using that $E^+(x) = z$ for all $z \in V^+$,

$$n_g(x) = d_g(x)\tilde{E}^+(g, x) = d_g(x)(g, x).$$

Since $d_g(x)$ is invertible, it follows that $g \cdot x = d_g(x)^{-1}n_g(x)$. 

Theorem 2.8. Let \( g \in \text{Aut}(g) \) and \( x \in V^+ \). Then \( g.x \in V^+ \) if and only if \( d_g(x) \) and \( e_g(x) \) are invertible, and then the value \( g.x \in V^+ \) is given by

\[
g.x = d_g(x)^{-1} n_g(x).
\]

Using matrix notation (1.4) and replacing \( g \) by \( g^{-1} \), this can explicitly be written as an action of \( \text{Aut}(g) \) on \( V^+ \) by “fractional quadratic maps”: if \( g^{-1}.x \in V^+ \), then

\[
g^{-1} x = (g_{11} - \text{ad}(x) \circ g_{01} + \frac{1}{2} \text{ad}(x)^2 \circ g_{-1,1})^{-1} \left( g_{00} - \text{ad}(x) \circ g_{00} + \frac{1}{2} \text{ad}(x)^2 \circ g_{-1,0} \right)(E).
\]

Proof. For the first claim, see Corollary 1.10, and the second claim is proved by the calculation preceding the statement of the theorem.

Using the formulas (1.16) for the denominators and (2.14) for the nominators, we can now explicitly describe the fractional quadratic action of the generators of \( G \):

\[
\begin{align*}
g & = e^{\text{ad}(v)} : \quad g(x) = x + v \\
g & = e^{\text{ad}(w)} : \quad g(x) = (\text{id} + \text{ad}(x) \circ \text{ad}(w) + \frac{1}{2} \text{ad}(x)^2 \circ \text{ad}(w)^2)^{-1}(x - \frac{1}{2} \text{ad}(x)^2 w) \\
g & = h : \quad g(x) = h_{11} x.
\end{align*}
\]

2.9. The automorphism group. The group \( \text{Aut}(g, D) \) acts on \( V^+ \times V^- \) by

\[
\begin{align*}
\text{Aut}(g, D) & \rightarrow \text{GL}(V^+) \times \text{GL}(V^-), \\
h & \mapsto (h_{11}, h_{-1,-1}) = (d_h(o^+), c_h(o^-)) = (d_h(o^+)^{-1}, c_h(o^-)).
\end{align*}
\]

We denote by \( \text{Aut}_a(V^+, V^-) \subset \text{GL}(V^+) \times \text{GL}(V^-) \) the image of this homomorphism (this is the automorphism group of the associated Jordan pair, see Section 3.1), and by \( \text{Str}(V^+) := p_{11} \circ \text{Aut}_a(V^+, V^-) \circ \iota_1 \) its projection to the first factor (sometimes called the structure group of \( V^+ \)).

Theorem 2.10. If \( x \in V^+ \) and \( g \in \text{Aut}(g) \) satisfy \( g.x \in V^+ \), then \( d_g(x) \in \text{Str}(V^+) \); more precisely,

\[
(d_g(x)^{-1}, c_g(x)) \in \text{Aut}_a(V^+, V^-).
\]

Proof. If \( g.x \in V^+ \), then \( g' := g e^{\text{ad}(x)} \) belongs to the set \( \Omega^+ \subset G \) defined in Theorem 1.12. According to Part (4) of this theorem, we decompose

\[
g' = e^{\text{ad}(v)} h e^{\text{ad}(w)}
\]

with a unique \( h = h(g, x) \in H \) depending on \( g \) and \( x \). From the definition of the (\( e^-\)) denominators it follows then that

\[
d_g(x) = d_{g'}(0) = h_{11}^{-1}, \quad e_g(x) = e_{g'}(0) = h_{-1,-1},
\]

and hence \( (d_g(x)^{-1}, c_g(x)) = (h_{11}, h_{-1,-1}) \in \text{Aut}_a(V^+, V^-) \).

As remarked after Proposition 2.6, the linear map \( d_g(x)^{-1} \) can also be interpreted as the tangent map of \( g \) at \( x \), and so Theorem 2.10 means that \( \text{Aut}(g) \) acts on \( X^+ \) by mappings that are conformal with respect to the linear group \( \text{Str}(V^+) \) (in the sense defined in [Be00, Section VIII.1.2]). In some cases this already characterizes the group \( \text{Aut}(g) \) as “the conformal group of \( X^+ \); this is the content of the Liouville theorem, see [Be00, Ch. IX].
3. The Jordan theoretic formulation

3.1. Jordan pairs. If \((g, D)\) is a 3-graded Lie algebra and \(V^\pm = g_{\pm 1}\), the following \(K\)-trilinear maps are well-defined:

\[
T^\pm : V^\pm \times V^\mp \times V^\mp \rightarrow V^\pm,
\]

\[(X, Y, Z) \mapsto T^\pm (X, Y, Z) := -[[X, Y], Z] = \text{ad}(Z)\text{ad}(X)Y,
\]
and they satisfy the following identities, where we use the notation \(T^\pm (X, Y, Z) := T^\pm (X, Y, Z)\):

\[
T^\mp (X, Y, Z) = T^\pm (Z, Y, X),
\]

\[
T^\pm (X, Y)T^\pm (U, V, W) = T^\pm (T^\pm (X, Y, U), V, W) - T^\pm (U, T^\pm (Y, X, V), W) + T^\pm (U, V, T^\pm (X, Y, W)),
\]

which mean that \((V^+, V^-), (T^+, T^-)\) is a linear Jordan pair over \(K\) (if 2 and 3 are invertible in \(K\), these two identities imply all other identities valid in Jordan pairs, cf. [Lo75, Prop. 2.2(b)]).

In the following we shall omit the adjective linear, when dealing with Jordan pairs. Conversely, if \((V^+, T^+)\) is a Jordan pair over \(K\), then for \(v \in V^\pm\) and \(w \in V^\mp\) we define the operator \((v, w) \in \text{End}(V^\pm)\) by \(T^\pm (v, w) : = T^\pm (v, w, x)\) and let \(\text{idr}(V^+, V^-) \subseteq gl(V^+) \times gl(V^-)\) be the Lie subalgebra generated by the operators \((-T^+(v, w), T^-(w, v)), v \in V^+, w \in V^-\). The elements of this Lie algebra are called inner derivations. The algebra of derivations of \((V^+, V^-)\) is defined by

\[
\text{der}(V^+, V^-) = \{(A^+, A^-) \in \text{End}_K(V^+) \times \text{End}_K(V^-) : (\forall u, v, w) A^+ T^\pm (u, v, w) = T^\pm (u, A^+ v, w) + T^\pm (u, A^- v, w) + T^\pm (u, A^\pm w)\},
\]

and it follows from (3.2) that it contains \(\text{idr}(V^+, V^-)\). Clearly, it contains also the element

\[
E := (\text{id}_{V^+}, - \text{id}_{V^-}),
\]

called the Euler operator of the Jordan pair \(V^\pm\).

If we are given a Jordan pair \((V^+, V^-)\), and \(g_0 \subseteq \text{der}(V^+, V^-)\) is a Lie subalgebra containing all inner derivations, then there is a unique structure of a 3-graded Lie algebra on \(V^+ \oplus g_0 \oplus V^-\) whose associated Jordan pair is \((V^+, V^-)\), and where the bracket satisfies

\[
[v, w] = (-T^+(v, w), T^-(w, v)), \quad v \in V^+, w \in V^-\]

and the grading element is the Euler operator \(E\) given by (3.4). The subalgebra

\[
\text{TKK}(V^+, V^-) := V^+ \oplus (\text{idr}(V^+, V^-) + KE) \oplus V^-
\]
is called the Tits–Kantor–Koecher algebra of the Jordan pair \((V^+, V^-)\). This choice for the 3-graded Lie algebra associated to \((V^+, V^-)\) has the advantage that \(\text{id}(g) = 0\).

The preceding construction may also be interpreted in the context of Lie triple systems (cf. e.g. [B00, Sect. III.3]): it is essentially the standard imbedding of the (polarized) Lie triple system \(q := V^+ \oplus V^-\) into the corresponding Lie algebra \(g = q \oplus [q, q]\). The standard imbedding yields a bijection between Lie triple systems and Lie algebras with involution, generated by the \(-1\)-eigenspace of the involution. See Chapter 6 concerning functorial properties of these constructions.

For any \(g_0\) as above, the representation of \(g_0\) on \(g_{-1} \oplus g_1\) will be faithful, so that \(\text{id}(g) \cap g_0 = \{0\}\). It may happen for central extensions \(\hat{g}\) of \(g\) that the corresponding subalgebra \(\hat{g}_0\) does not act faithfully on \(\hat{g}_{-1} \oplus \hat{g}_1 \cong g_{-1} \oplus g_1\) (see Chapter 7).
3.2. Projective elementary group and projective completion. For the rest of Chapter 3, we fix a Jordan pair \((V^+, V^-)\) and let \(g := TKK(V^+, V^-)\). The projective elementary group \(PE(V^+, V^-) := G(\text{ad}(E))\) is defined as in Section 1.2. Using the notation, with \(x, y \in V^\pm, v \in V^\pm\),

\[
Q^\pm(x) := \frac{1}{2} \text{ad}(x)^2 v = \frac{1}{2}[x, [x, v]]
\]

\[
Q^\pm(x, y) := Q^\pm(x + y) - Q^\pm(x) - Q^\pm(y) = \text{ad}(x)\text{ad}(y) : V^\mp \rightarrow V^\pm,
\]

the operators \(e^{ad_x} = 1 + \text{ad} x + \frac{1}{2}(\text{ad} x)^2\) \((x \in V^\pm)\) are given in matrix notation by Equation (1.5), with \(\frac{1}{2}\text{ad}(x)^2\) replaced by \(Q^\pm(x)\) and \(\frac{1}{2}\text{ad}(y)^2\) replaced by \(Q^\pm(y)\). Our definition of \(PE(V^+, V^-)\) follows the one by O. Loos from [Lo95]. The projective linear group of a Jordan pair has been introduced by Faulkner in [Fa83] in a slightly different context (without Euler operator). The groups \(P^\pm\) and the spaces \(X^\pm = G/P^\pm\) are defined as in Section 1.11; the embedding \(V^\mp \times V^- \rightarrow X^+ \times X^-\) is called the projective completion of the Jordan pair \((V^+, V^-)\).

3.3. The Bergman operator. Recall from Section 2.2 the canonical kernel: for \((x, y) \in X^+ \times X^-
\]

\[
K_{x,y} : T_x X^- \rightarrow T_y X^+, \quad Y \mapsto Y_z.
\]

Of course, there is a similarly defined map \(K_{y,z}\); we will also use the notation \((K_{x,y}^+, K_{y,z}^-)\) for \((K_{x,y}, K_{y,z})\). Using the description via associated bundles, the kernel is given by

\[
K_{g_1, p-g_2, p^+} : T_{g_2}^p X^- \rightarrow T_{g_1} p^- X^+, \quad [g_2, v] \mapsto [g_1, p_{r_1}(g_1^{-1} g_2, v)],
\]

and hence the trivialized picture is

\[
K_{x,y}^+ = (e^{-ad_x}e^{ad_y})_{11} = d_{\text{exp} -y}(x) : V^+ \rightarrow V^+.
\]

In matrix form,

\[
e^{-ad_x}e^{ad_y} = \begin{pmatrix} 1 & \text{ad}(x) & Q^+(x) \\ 0 & 1 & -\text{ad}(x) \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ \text{ad}(y) & 1 & 0 \\ Q^-(y) & \text{ad}(y) & 1 \end{pmatrix},
\]

so that we get for the coefficient with index 11, using that on \(V^+\) we have for \(x \in V^+\) and \(y \in V^-\) the relation \(\text{ad} x \text{ad} y = \text{ad}[x, y] = -T^+(x, y)\):

\[
K_{x,-y}^+ = B_+(x, y) = id_{V^+} - T^+(x, y) + Q^+(x)Q^-(y).
\]

We likewise get

\[
K_{x,-y}^- = B_-(y, x) = id_{V^-} - T^-(y, x) + Q^-(y)Q^+(x)
\]

(cf. the definition in (1.17)). This expression is known as the Bergman operator of the Jordan pair \((V^+, V^-)\). Theorem 2.3 now implies that the pair \((v, w)\) is transversal if and only if \((B_+(v, -w), B_-(w, v))\) is invertible in \(\text{End}(V^+) \times \text{End}(V^-)\). It is known in Jordan theory that \(B_+(v, -w)\) is invertible if and only if it is \(B_+(v, w) \) (the symmetry principle, cf. [Lo75, Prop. 1.3.3]), and hence \((v, w)\) is transversal if and only if \(B_+(v, -w)\) is invertible. So far we do not know a "Lie theoretic" proof of this fact.

3.4. The quasi-inverse. Let \(y \in g_{-1}\). Then for \(g = e^{ad(y)}\) and \(x \in V^+\), Formulae (1.16) and (2.14) show that denominator and nominator of \(g\) are given by

\[
d_g(x) = B_+(x, y), \quad n_g(x) = x - Q^+(x)y
\]

and hence, according to Theorem 2.8, \(g(x) \in V^+\) if and only if \((B_+(x, y), B_-(y, x))\) is invertible, and then

\[
g \cdot x = B_+(x, y)^{-1}(x - Q^+(x)y).
\]
Following [Lo77], we will use also the notation $t_v(x) = x + v$ for translations on $V^+$ and

$$
\tilde{t}_w(x) := e^\text{ad}(w) x = B_+(x, w)^{-1}(x - Q^+(x)w)
$$

(3.13)

for "dual translations" or "quasi-inverses". In Jordan theory the notation $x^y := e^\text{ad}y x$ is also widely used (cf. [Lo75]), and one says that $(x, y)$ is quasi-invertible if $(B_+(x, y), B_-(y, x))$ is invertible, i.e., if $(x, -y)$ is a transversal pair. Our definitions of the Bergman operator via the canonical kernel and of the quasi-inverse are natural in the sense that they have natural transformation properties with respect to elements $g$ of the group Aut$(g)$; taking for $g$ typical generators of $G$, we get Jordan theoretic results such as the "shifting principle" (see [Be00, Section VIII.A] for the precise form of the argument).

### 3.5. Automorphism and structure group.

The group Aut$_\varphi(V^+, V^-)$ defined in Section 2.9 coincides for $g = \text{TKK}(V^+, V^-)$ with the automorphism group Aut$(V^+, V^-)$ of $(V^+, V^-)$ in the Jordan theoretic sense. It follows from Theorem 2.10 that if $(x, -y)$ is transversal, then $\beta(x, y) := (B_+(x, y), B_-(y, x))^{-1}$ belongs to Aut$(V^+, V^-)$. The subgroup generated by these elements is called the inner automorphism group. Projecting to the first factor, one gets the structure group, resp. the inner structure group of $V^+$.

### 3.6. Jordan fractional quadratic transformations.

An End$(V^+)$-valued Jordan matrix coefficient (of type $(1, 1)$, resp. of type $(1, 0)$) is a map of the type

$$
q : V^\sigma \times V^\nu \to \text{End}(V^+), \quad (x, y) \mapsto (e^{\text{ad}(x)} g e^{\text{ad}(y)} h)_{11},
$$

where $\sigma, \nu \in \{\pm\}$ and $g, h$ belong to the extended elementary projective group $G^{\text{ext}}$ (cf. Section 1.2), resp.

$$
p : V^\sigma \times V^\nu \to V^+, \quad (x, y) \mapsto (e^{\text{ad}(x)} g e^{\text{ad}(y)} h)_{10} E.
$$

These maps are quadratic polynomials in $x$ and in $y$. Nominators and denominators of elements of $G$ are partial maps of maps of the type of $p$ or $q$ by fixing one of the arguments to be zero. A Jordan fractional quadratic map is a map of the form

$$
f : V^\sigma \times V^\nu \supset U \to V^+, \quad (x, y) \mapsto q(x, y)^{-1} p(x, y),
$$

where $q, p$ are Jordan matrix coefficients of type $(1, 1)$, resp. $(1, 0)$, and $U = \{(x, y) \in V^\sigma \times V^\nu : q(x, y) \in \text{GL}(V^+)\}$. In the following, we also use the notation $\exp(x) := e^{\text{ad}(x)}$ for $x \in V^\pm$.

**Theorem 3.7.** The actions

$$
V^+ \times X^+ \to X^+ \quad \text{and} \quad V^- \times X^+ \to X^+
$$

are given, with respect to all charts from the atlas $A$ (cf. Eqn. (2.6)), by Jordan fractional quadratic maps. In other words, for all $g, h \in G$, the maps

$$(v, y) \mapsto (h \circ \exp(v) \circ g) y, \quad (w, y) \mapsto (h \circ \exp(w) \circ g) y$$

are Jordan fractional quadratic.

**Proof.** As to the first action, we write

$$
(h \circ \exp(v) \circ g) y = (d_{h \circ \exp(v) \circ g}(y))^{-1} n_{h \circ \exp(v) \circ g}(y) = q(v, y)^{-1} p(v, y)
$$

with

$$
q(v, y) = d_{h \circ \exp(v) \circ g}(y) = (e^{-\text{ad}(y)} g^{-1} e^{-\text{ad}(v)} h^{-1})_{11}
$$

and

$$
p(v, y) = n_{h \circ \exp(v) \circ g}(y) = (e^{-\text{ad}(y)} g^{-1} e^{-\text{ad}(v)} h^{-1})_{10} E,
$$

and hence the action is Jordan fractional quadratic. For the action of $e^{\text{ad}(V^-)}$, we use the same arguments.

We may say that $H_\infty := X^+ \setminus V^+$ is the "hyperplane at infinity"; then $H_\infty$ is stable under the action of $V^+$. In case $(X^+, X^-) = (\mathbb{R}^n, (\mathbb{R}^n)^*)$ is an ordinary projective geometry, the action of the translation group on the hyperplane at infinity is the trivial action. However, already in the case of more general Grassmannian geometries this is no longer true, as can be seen from the explicit formulas for this case given in [Be01].
Corollary 3.8. With respect to the charts from the atlas $A$, the structure maps $\mu_r$ for $r \in \mathbb{K}^\times$ defined in Section 1.14 are given by a composition of Jordan fractional quadratic maps and diagonal maps $\delta(x) = (x, x)$.

Proof. According to [Be02, Cor. 5.8], the multiplication maps can be written as a composition of maps of the type described in the preceding theorem, diagonal maps and one dilation $h^{(D,r)}$ (defined in Section 1.2). But this dilation comes from an element of $G^\text{ext}$ and hence the composition with such a dilation is again Jordan fractional quadratic.  

3.9. Case of a general base ring. Even if $\mathbb{K}$ is a general base ring (i.e., possibly with 2 or 3 not invertible), there still is a 3-graded Lie algebra $\mathbb{T}_K(V^+, V^-)$ and a group $\mathbb{P}_E(V^+, V^-)$ associated to a general (quadratic) Jordan pair, cf. [Lo95]. The main difference is that in the matrix expression of $\text{ad}(x)$ ($x \in \mathfrak{g}_1$) the term $\frac{1}{2} \text{ad}(x)^2$ has to be replaced by $Q^+(x)$. Once one has checked that the abelian groups $U^\pm$ obtained in this way are well-defined groups of automorphisms, one can essentially proceed as we did in Chapter 1, replacing the space $\mathcal{G}$ by the $\mathbb{P}_E(V^+, V^-)$-orbit of $\text{ad}(E)$ in $\text{der}(\mathfrak{g})$ and the space $\mathcal{F}$ by the space of inner filtrations belonging to gradings from $\mathcal{G}$.

4. Involutions, symmetric spaces, and Jordan triple systems

4.1. Symmetric spaces attached to a Lie algebra. An (abstract) reflection space is a set $S$ together with a map $\mu : S \times S \to S$ such that, if we let $\sigma_x(y) := \mu(x, y)$,

- (S1) $\mu(x, x) = x$ 
- (S2) $\sigma_x^2 = \text{id}_S$ 
- (S3) $\sigma_x$ is an automorphism of $\mu$, i.e. $\sigma_x(\mu(y, z)) = \mu(\sigma_x(y), \sigma_x(z))$.

(Differentiable reflection spaces, i.e. manifolds with a smooth reflection space structure $\mu$, have been introduced by O. Loos in [Lo67]). In Part II ([BN03]) of this work we define a symmetric space (over $\mathbb{K}$) to be a reflection space $(S, \mu)$ such that $S$ is a smooth manifold over $\mathbb{K}$ (in the sense of [BGN03]) and $\mu$ is smooth and satisfies

- (S4) the tangent map $T_x\sigma_x$ at $x$ is given by $-\text{id}_{T_xS}$.

(See [BN03] for the basic theory of symmetric spaces and for a comparison with the approach by O. Loos [Lo69].) To any Lie algebra $\mathfrak{g}$ over $\mathbb{K}$ we may associate a reflection space as follows. Let $S = \mathcal{G} = \{ D \in \text{der}(\mathfrak{g}) : D^2 = D \}$ be the space of 3-gradings of $\mathfrak{g}$ and recall from Section 1.2 the definition of the extended projective elementary group $G^\text{ext}$ which is generated by its normal subgroup $\mathcal{G}$ and the subgroup $\{ h^{(D,r)|r \in \mathbb{K}^\times} \}$. Taking $r = -1$, we get the reflection elements

$$ \sigma^{(D)} := h^{(D,-1)} = 1 - 2D^2 \in \text{Aut}(\mathfrak{g}, D).$$  

(4.1)

We define the map $\mu$ by

$$ \mu : S \times S \to S, \quad \mu(D,D') := \sigma^{(D)}D'\sigma^{(D)} = (1 - 2D)D'(1 - 2D).$$  

(4.2)

Then (S1) follows from the fact that $D$ and $\sigma^{(D)}$ commute, (S2) holds because $\sigma^{(D)}$ is an involution, and (S3) follows from the fact that $\text{Aut}(\mathfrak{g})$ clearly acts as a group of automorphisms of $\mu$, and all reflection elements $\sigma^{(D)}$ belong to $\text{Aut}(\mathfrak{g})$. It is clear that the subset $\mathcal{G} \subset \mathcal{G}$ is stable under $\mu$. Also, $M \subset \mathcal{G}$ is stable under $\mu$ because $M$ is stable under the action of $G^\text{ext}$ (Theorem 1.12 (3)), and $G^\text{ext}$ contains the reflection element $\sigma^{(D)}$ corresponding to the base point and hence contains all reflection elements corresponding to points of $M$. Property (S4) is also satisfied in a purely algebraic sense: since $\sigma^{(D)}$ acts by $-1$ on the complement $\mathfrak{g}_\mp$ of $\mathfrak{g}_\pm \oplus \mathfrak{g}_0$, it follows readily from the definition of the tangent map in Section 2.1 that

$$ T_{+\langle D \rangle} \sigma^{(D)} = -\text{id}_{T^+_{(D)}} \mathcal{F}, \quad T_{-\langle D \rangle} \sigma^{(D)} = -\text{id}_{T^-_{(D)}} \mathcal{F}, $$

$\mathcal{F}$.
and hence the tangent map $T_D (\sigma (D))$ will be minus one if we define tangent map and tangent space at $D$ to be the direct product of the ones defined with respect to $f^+ (D)$ and $f^- (D)$.

The restriction of $\mu$ to $\mathcal{G} \times \mathcal{G}$ is related to the ternary map $\mu_{-1}$ from Section 1.13 as follows: assume $D_1$ corresponds to the transversal pair $(f_1, f_2)$ and $D_2$ to the transversal pair $(f_3, f_4)$. Then

$$
\mu((f_1, f_2), (f_3, f_4)) = \mu_{-1}(f_1, f_2, f_3), \mu_{-1}(f_1, f_2, f_4)) = (h^{(D_{-1})}, f_3, h^{(D_{-1})}, f_4),
$$

which is the same as the product map on $M$ considered in [Be02, Cor. 4.4].

4.2. Involutions and symmetric subspaces. An involution of a 3-graded Lie algebra is a Lie algebra automorphism $\theta$ of order 2 reversing the grading, i.e., such that $\theta (g_{\pm 1}) = g_{\mp 1}$ and $\theta (g_0) = g_0$. An involution $\theta$ induces by conjugation an automorphism of the elementary projective group $G$, again denoted by $\theta$, such that $\theta (P^-) = P^+$. Therefore it induces a bijection

$$p: X^+ \to X^-, \quad gP^- \mapsto \theta (g)P^+,$$

compatible with the map $\mathcal{F} \to \mathcal{F}$, $f \mapsto \theta (f)$, and such that $p (\sigma ^+) = \sigma^-$. We say that $f \in \mathcal{F}$ is non-isotropic (with respect to $\theta$) if $\theta (f) \cap f = \emptyset$. In particular, the base point $\sigma ^+ = f^+$ is non-isotropic; thus there exist non-isotropic points, and $p$ is a polarity in the sense of [Be02]. Since $\theta$ is an automorphism normalizing $G$, the spaces $\mathcal{G}$ and $M \subset \mathcal{G}$ are stable under $\theta$, and the naturality of the product $\mu$ implies that $\theta$ is an automorphism of $\mu$. Therefore the $\theta$-fixed subspace $M^\theta$ is a symmetric subspace of $M$, which as a set is in bijection with the set of non-isotropic points of $X^+$, i.e.,

$$M^{(\theta)} := \{ f \in X^+: \text{non-isotropic w.r.t. } \theta \} \to M^\theta, \quad f \mapsto (f, \theta f)$$

is a bijection. By forward transport of structure, the symmetric space structure of $M^\theta$ corresponds to the structure on $M^{(\theta)}$ given by

$$\mu(x, y) = \mu_{-1}(x, p(x), y)$$

(this is the formula used in [Be02] to define the symmetric space structure). The symmetry w.r.t. the point $x$ is now induced by the element $\sigma (D)$, where $D \in \mathcal{G}$ corresponds to the point $(x, \theta (x)) \in \mathcal{G}$; as noticed above, the algebraically defined tangent map $T_x (\sigma (D))$ equals minus the identity, and hence (S4) is again satisfied in an algebraic sense.

Theorem 4.3. For a fixed polarity $p: X^+ \to X^-$, we identify $X^+$ and $X^-$ via $p$. Then the multiplication map $\mu$ on $M^{(\theta)}$ is a composition of Jordan fractional quadratic maps and diagonal maps $\delta (x) = (x, x)$.

Proof. By Corollary 3.8, the map $\mu_{-1}$ is of the form mentioned in the claim. According to Formula (4.5), $\mu$ is related to $\mu_{-1}$ via

$$\mu(x, y) = \mu_{-1}(x, x, y), \quad \text{i.e., } \mu = \mu_{-1} \circ (\delta \times \text{id}),$$

which proves the claim.

In [BN03] it will be shown that Theorem 4.3 implies, in very general situations, smoothness of $\mu$.

4.4. Involutions and Jordan triple systems. If $\theta$ is an involution of the 3-graded Lie algebra $g$, the trilinear map on $V^+$ defined by

$$T(X, Y, Z) := -[[X, \theta (Y)], Z]$$

is a Jordan triple product, i.e., it satisfies the identities (3.1) with the superscripts $\pm$ omitted. Conversely, given a Jordan triple system over $K$ (abbreviated JTS) (i.e., a $K$-module with a $K$-trilinear map satisfying the above mentioned identities), we can define an involution on the Lie algebra $V^+ \oplus \text{der}(V^+, V^-) \oplus V^-$ by

$$\theta (v, (A, B), w) = (w, (B, A), v),$$

and the associated JTS is the one we started with. In this way we get a bijection between Jordan triple systems over $K$ and minimal 3-graded Lie algebras with involution (see Section 1.1).
5. Self-dual geometries and Jordan algebras

5.1. Self-dual geometries. We fix a 3-graded Lie algebra \( \mathfrak{g} \) with grading induced by the Euler operator \( E \). Recall our realization of \( X^+ \) and \( X^- \) as \( G \)-orbits in the space \( \mathcal{F} \) of 3-filtrations of \( \mathfrak{g} \). Two cases can arise: either \( X^+ \cap X^- \) is empty, or \( X^+ = X^- \). In the latter case we let \( X := X^+ = X^- \), and again two cases are possible: either

(a) \( V^+ \cap V^- \) is empty, or
(b) \( V^+ \cap V^- \) is not empty; then we say that the geometry given by \( (\mathfrak{g},E) \) is self-dual, and we let \( V^X := V^+ \cap V^- \).

An equivalent characterization of self-dual geometries is: there are three points \( f_1, f_2, f_3 \in X^+ \) such that \( f_1 \cap f_2, f_2 \cap f_3, f_3 \cap f_1 \) (namely, take \( (f_1, f_2) = (f^-) \) to be the base point and \( f_3 \) some element of \( V^+ \cap V^- \)).

5.2. The Jordan inverse. Assume that \( (\mathfrak{g},E) \) is self-dual and fix some point \( f \in V^+ \cap V^- \). We claim that there exists an involution \( j \) of \( \mathfrak{g} \) (cf. Section 4.2) such that \( j(V^+) \cap V^- \neq \emptyset \). In fact, let \( W := f^+ \); then \( W \subset X \) carries a natural structure of an affine space over \( \mathbb{K} \) (Theorem 1.12(3)), and by assumption \( o^+ \) and \( o^- \) belong to \( W \). Let \( e \in W \) be the midpoint of \( o^+ \) and \( o^- \) in the affine space \( W \). Since \( e \in W \), the pair \( (e,f) \) is transversal and hence corresponds to a 3-grading \( \mathfrak{g} = \mathfrak{g}^1 \oplus \mathfrak{g}^0 \oplus \mathfrak{g}^1 \), i.e. to an element \( D' \in G \). Let \( j := h(D',-1) \in G^{ext} \) be the automorphism that is minus one on \( \mathfrak{g}^1 \oplus \mathfrak{g}^1 \) and one on \( \mathfrak{g}^0 \). Then \( j \) fixes \( (e,f) \) and acts by the scalar minus one on the \( \mathbb{K} \)-module \( W \) with zero vector \( e \). Since \( e \) is the midpoint of \( o^+ \) and \( o^- \), it follows that \( j(o^-) = o^+ \), and since obviously \( j \) is of order two, it is an involution. The condition \( j((f^+)^{-1}) = f^+ \) implies that \( j(V^+) = j((f^+)^{-1}) = (f^-)^{-1} = V^- \). In particular, \( V^+ \cap j(V^+) = V^+ \cap V^- = V^X \) is non-empty by assumption. It contains the point \( e = j(e) \).

Now we apply Theorem 2.8 in order to derive an explicit formula for \( j \) in the chart \( V^+ \); for \( v \in \mathfrak{g}_1 \), let \( v = jv \in \mathfrak{g}_{-1} \); by Equation (2.12), \( v \) gives rise to the homogeneous quadratic vector field \( v^+(x) = Q^+(x)v \) on \( V^+ \). From Proposition 2.6 we now get

\[
d_j(x)v = (j^{-1}v)(x) = v^+(x) = Q^+(x)v.
\]

In a similar way we see that \( c_j(x) = Q^-(x)v \). (In fact, since \( j \) is an involution, \( c_j(x) = jd_j(-x)j = jd_j(x)j \), and this is invertible if and only if \( j \) is invertible.) Corollary 1.10 now shows that \( j(x) \in V^+ \) if and only if \( x \) belongs to the set

\[
V^X = \{ x \in V^+: Q^+(x) \text{ invertible} \},
\]

which is called the set of invertible elements in \( V^+ \). The nominator of \( j \) is \( n_j(x) = -x \) since \( j \) reverses the grading (i.e. \( jE + E \in j(\mathfrak{g}) \)). Now Theorem 2.8 shows that, for \( x \in V^X \), \( j(x) = -Q^+(x)^{-1}x \). The map

\[
V^X \to V^X, \quad x \mapsto j(x) := -Q^+(x)^{-1}x
\]

is known as the Jordan inverse.

5.3. Jordan algebras. Notation being as above, note that by construction \( e \) is a fixed point of \( j \), i.e., we have \( e = j(e) = -Q(e)e \). The tangent map \( T_e j \) is \( -id_{T_e X^+} \). Now 2.11 implies that also

\[
d_j(e) = T_e(-id_W) = -id_{V^+}.
\]

In conclusion, we have a Jordan triple system with an element \( e \) such that \( Q(e) = -id_V \). It is is known that then

\[
x \cdot y := -\frac{1}{2}T(x,e,y)
\]
defines a Jordan algebra structure on $V$ with unit element $e$. Conversely, every unital Jordan algebra arises in this way (cf. [Lo75, I.1.10]).

5.4. The self dual geometry associated to a unital Jordan algebra. Now assume that $(g, E)$ is 3-graded and there exists $e^– \in g_{–1}$ such that $Q^–(e^–) : V^+ \to V^–$ is a bijection. Let $g := e^{\text{ad}(e^–)}$. We claim that the flag $f^+ : g_1 \subset g_0 \oplus g_1$ is transversal to the flag $g(f^+)$: first of all, for $v \in g_1$, 

$$\text{pr}_{–1}(g(v)) = \text{pr}_{–1}(v + [e^–, v] + Q^–(e^–)v) = Q^–(e^–)v,$$

hence $\text{pr}_{–1} g \circ \text{id}$ is bijective and thus $g(g_1)$ is a complement of $g_1 \oplus g_0$. Next, $g(g_1 \oplus g_0)$ is a complement of $g_1$: equivalently, $e^{–\text{ad}(e^–)}g_1$ is a complement of $g_0 \oplus g_1$, which is true by the same argument. Hence, $gf^+ \cap f^+$. With $(o^+, o^–) = (f^–, f^+)$, this means that $g(o^–) \in V^+ \subset X^+$, but since $g \in G$, this means that $X^– = X^+$. Moreover, $o^– \in V^–$, and $e^{\text{ad}(e^–)}$ acts as a translation on $V^–$; therefore $g.o^– \in V^– \cap V^+$, and it follows that the geometry is self-dual. – Summing up:

Theorem 5.5. For a Lie algebra $g$ with Euler operator $E$, the following are equivalent:

1. The geometry given by $(g, E)$ is self-dual.
2. There is an involution $j$ of $(g, E)$ such that $j(V^+ \cap V^–) \neq \emptyset$.
3. The Jordan pair $(V^+, V^–)$ contains invertible elements.
4. The Jordan pair $(V^+, V^–)$ comes from a unital Jordan algebra $(V, E)$.

Proof. (1) $\Rightarrow$ (2) $\Rightarrow$ (3) has been shown in 5.2, and (3) $\Rightarrow$ (1) has been shown in 5.4. The equivalence of (3) and (4) is well-known (cf. [Lo75, I.1.10]; see 5.3).

We do not know whether the condition $X^+ = X^–$ alone already implies that $V^+ \cap V^– \neq \emptyset$ – in the finite-dimensional case over a field this certainly is true since then the “hyperplane at infinity” $X^+ \setminus V^+$ is an algebraic hypersurface, and hence $V^+$ and $V^–$ must intersect if they are both included in $X^+$. However, in infinite dimension the “hyperplane at infinity” may become rather “big” and may very well contain some affine parts – this problem is also discussed in [Be03].

6. Functorial properties

6.1. Functoriality problems. So far we have considered the following categories: Jordan pairs $(V^+, V^–)$ over $K$, 3-graded Lie algebras $(g, D)$ over $K$, generalized projective geometries $(X^+, X^–)$ (these may be defined here simply as the geometries $(X^+, X^–)$ associated to a 3-graded Lie algebra); associated reflection spaces $(M, \mu)$; elementary projective groups $G = G(g, D)$ associated to 3-graded Lie algebras. What are the functorial relations between these categories? It is obvious that homomorphisms of 3-graded Lie algebras induce, by restriction to the pair $(g_1, g_{–1})$, homomorphisms of Jordan pairs. Other functorially problems are less trivial:

(FP1) When does a homomorphism of Jordan pairs induce a homomorphism of the associated Tits-Kantor-Koecher algebras?

(FP2) When does a homomorphism of Jordan pairs induce a homomorphism of the associated generalized projective geometries, resp. of the associated reflection spaces?

(FP3) When does a homomorphism of Tits-Kantor-Koecher algebras induce a homomorphism of the associated elementary projective groups?

(FP4) When does a homomorphism of general 3-graded Lie algebras induce a homomorphism of the associated elementary projective groups?

6.2. Functoriality of the Tits-Kantor-Koecher algebra. In general, a homomorphism of Jordan pairs does not induce a homomorphism of the associated Tits-Kantor-Koecher algebra. In fact, as remarked in Section 3.1, the Tits-Kantor-Koecher algebra $\text{TKK}(V^+, V^–)$ may be seen as the standard embedding of the polarized Lie triple system $V^+ \oplus V^–$; but the standard embedding of a Lie triple system does in general not depend functorially on the Lie triple system.
63. Functoriality of the projective geometry and of the reflection spaces. Any Jordan pair homomorphism \( \varphi^\pm : V^\pm \to (V')^\pm \) induces, in a functorial way, a well-defined map of geometries

\[
\widetilde{\varphi}^\pm : X^\pm \to (X')^\pm,
\]

where \( \varphi \in V^+, w_i \in V^-, i = 1, \ldots, k, k \in \mathbb{N} \) (cf. [Be00, Th. 10.1]); the main point here is that the geometry \( (X^\pm, X^-) \) can be described by generators (namely \( (V^+, V^-) \)) and relations (with respect to the product maps \( \mu_r \) from Section 1.13), and Jordan pair homomorphisms are compatible with the relations. (If the geometry is stable in the sense of [Lo95], then these relations are given by projective equivalence, cf. [Lo77], [Lo95].) A homomorphism of geometries in the sense of [Be00] induces a homomorphism of the corresponding reflection spaces (because the reflection space structure is defined via the maps \( \mu_r \)); therefore Jordan pair homomorphisms always induce homomorphisms of associated reflection spaces.

In particular, an isomorphism of Jordan pairs induces a bijection of geometries. Therefore, if two 3-graded Lie algebras have the same Jordan pair \( (g_1, g_{-1}) \), then there is a canonical bijection between the associated geometries. (Cf. Th. 6.6 below for another, elementary proof.) In particular, as long as we are only interested in the associated geometry \( (X^+, X^-) \) (e.g., in Part II of this work) we may without loss of generality assume that \( g \) is a Tits-Kantor-Koecher algebra.

6.4. Functoriality problem for the projective elementary group. Let \( \varphi : g \to g' \) be a morphism of 3-graded Lie algebras. One would like to define a homomorphism \( \varphi : G \to G' \) of the associated elementary projective groups by requiring that \( \varphi(e^{ad(g^+)}) = e^{ad(g')} \), but in general this will not be well-defined. Therefore we introduce the group

\[
G(\varphi) := \{ g = (g_1, g_2) \in G \times G' : (\forall X \in g) \; g_2 \varphi(X) = \varphi(g_1 X) \}.
\]

Then the projection \( pr_1 : G(\varphi) \to G \) onto the first factor is surjective: in fact, the image of \( pr_1 \) contains the generators of \( G \) because all \( g_1 := e^{ad(x)}, x \in g^\pm \), preserve the ideal \( \ker(\varphi) \), and so with \( g_2 := e^{ad(\varphi(x))} \) the pair \( (g_1, g_2) \) belongs to \( G(\varphi) \). Since \( G \) is generated by \( e^{ad(g^+)} \), it follows that the projection \( pr_1 \) is surjective. The kernel of the projection \( pr_1 \) is given by all elements of the form \((1, g_2)\) where \( g_2 \) acts trivially on the subalgebra \( \varphi(g) \subseteq g' \). Therefore, if \( \varphi \) is surjective, then \( pr_1 \) is a bijection, and \( pr_2 \circ (pr_1)^{-1} : G \to G' \) is the desired homomorphism (see [Be00, Section 1.3] for similar considerations on the level of symmetric spaces). Combining with 6.2, we see that surjective Jordan pair homomorphisms induce (surjective) homomorphisms of associated elementary projective groups (this result is also contained in [Lo95, Prop. 1.6]).

The functoriality problem is now reduced to the case of injective homomorphisms. In good cases, one may then hope to recognize \( pr_1 : G(\varphi) \to G \) as a sort of covering of \( G \), and thus to view \( pr_2 \) as a sort of lift of the desired homomorphism to a covering group.

6.5. Problem (FP4) for isomorphisms of Jordan pairs. Let \( g \) be a 3-graded Lie algebra \( g \) with grading element \( E \) and \( g \subseteq g \) an inner 3-graded subalgebra containing \( g^\pm \). We denote by \( G \), resp. by \( \overline{G} \) the associated elementary projective groups. In the present section we will see that the injective homomorphism \( g \to g \) (which induces an isomorphism of associated Jordan pairs) induces a surjective homomorphism “in the opposite sense”: \( G \to G \). In particular we shall give another and more elementary proof of the fact that the associated homogeneous spaces are the same (cf. 6.3). As \( g \) contains \( g^\pm \), it is invariant under the group \( G \) generated by \( e^{ad(g^\pm)} \). Moreover, \( G \) acts trivially on the quotient space \( g/g^\pm \) because its generators have this property, i.e., \( g x = x \in g \) for each \( x \in g \) and \( g \in G \).

Theorem 6.6. There is a surjective restriction homomorphism

\[
R : G \to G, \quad g \to g|_{\overline{g}}, \quad \text{with} \quad R^{-1}(H) = H \quad \text{and} \quad R^{-1}(P^\pm) = P^\pm.
\]
For the corresponding homogeneous spaces, we have

\[ \frac{G}{P^\pm} \cong G/P^\pm \quad \text{and} \quad \frac{G}{H} \cong G/H \]

as homogeneous spaces of \( G \).

**Proof.** First we observe that \( R(U^\pm) = U^\pm \) implies that \( R \) is surjective.

Let \( \text{ad}_g : \mathfrak{g} \to \text{der}(\mathfrak{g}) \) be given by \( \text{ad}_g(x) := [x, g] \) and let \( E \) be an Euler operator defining the grading of \( \mathfrak{g} \), resp., an Euler operator \( E \in \mathfrak{g} \) defining the grading on \( \mathfrak{g} \). Then the ideal \( \text{ker} \text{ad}_g \) of \( \mathfrak{g} \) is invariant under \( \text{ad}_E \), hence adapted to the grading. For \( x \in \mathfrak{g}_\pm \) we have

\[ \text{ad}_x(x)(E') = [x, E'] = \pm x, \]

so that

\[ \text{ker} \text{ad}_x \subseteq \mathfrak{g}_0, \]

and in particular \( \text{ad}_x \) is injective on \( \mathfrak{g}_+ + \mathfrak{g}_- \). For \( x = x_+ + x_0 + x_- \) with \( x_\pm \in \mathfrak{g}_\pm \) and \( x_0 \in \mathfrak{g}_0 \) we have

\[ [\text{ad}_x E, \text{ad}_x x] = \text{ad}_x[E, x] = \text{ad}_x(x_+ - x_-). \]

If this bracket vanishes, then \( x_+ - x_- \in \text{ker} \text{ad}_x \subseteq \mathfrak{g}_0 \) implies \( x = x_0 \in \mathfrak{g}_0 \), i.e., we obtain the refined information

\[ \text{ker} \text{ad}_x \subseteq \text{ad}_x^{-1}(\mathfrak{g}_0 \setminus \mathfrak{g}_0) = \mathfrak{g}_0. \]

Now let \( g \in G \) with \( R(g) \in H \). For \( x \in \mathfrak{g}_0 \) we then have

\[ \text{ad}_x(g,x) = R(g) \circ \text{ad}_x(x) \circ R(g)^{-1}, \]

and all three factors on the right hand side commute with the grading derivation \( \text{ad}_x E \) of \( \mathfrak{g} \). Hence \( \text{ad}_x(g,x) \) commutes with \( \text{ad}_E \), and the argument from above implies that \( g \in \mathfrak{g}_0 \). On the other hand \( R(g) \) preserves the grading of \( \mathfrak{g} \), and hence in particular the subspaces \( \mathfrak{g}_\pm \). This means that \( g \) preserves all eigenspaces of \( ad E \) on \( \mathfrak{g} \), and therefore that \( g \) commutes with \( \text{ad}_E \), so that \( g \in H \). We conclude that \( R^{-1}(H) \subseteq H \), and the converse inclusion follows from the fact that the action of \( H \) on \( \mathfrak{g} \) preserves the grading \( \mathfrak{g} = \mathfrak{g}_+ \oplus (\mathfrak{g} \cap \mathfrak{g}_0) \oplus \mathfrak{g}_- \) of \( \mathfrak{g} \).

From \( P = HU^\pm \) and \( R(U^\pm) = U^\pm \), we obtain

\[ R^{-1}(P^\pm) = R^{-1}(H)U^\pm \subseteq HU^\pm = P^\pm. \]

Since \( R(P^\pm) = R(H)R(U^\pm) \subseteq HU^\pm = P^\pm \), the first assertion follows.

For the homogeneous spaces, we now get

\[ \frac{G}{P^\pm} \cong \frac{G}{R^{-1}(P^\pm)} = \frac{G}{P^\pm} \quad \text{and} \quad \frac{G}{H} \cong \frac{G}{R^{-1}(H)} = \frac{G}{H}. \]

7. Central extensions of three-graded Lie algebras

In this section \( K \) denotes a field with \( 2, 3 \in K^\times \).

**7.1.** Let \( \mathfrak{g} \) be a 3-graded Lie algebra with grading element \( E \). In this section we assume that \( \mathfrak{g} \) is generated by \( E \) and \( \mathfrak{g}_\pm \), i.e., that

\[ \mathfrak{g}_0 = K E + [\mathfrak{g}_+, \mathfrak{g}_-]. \quad (7.1) \]

We shall show that the homogeneous spaces associated of the elementary projective group of \( \mathfrak{g} \) do not change for central extensions. Combining these results with those of the preceding section, it follows that they only depend on the Jordan pair \( (\mathfrak{g}_+, \mathfrak{g}_-) \).
Lemma 7.2. Let $q: \widehat{\mathfrak{g}} \to \mathfrak{g}$ be a central extension of $\mathfrak{g}$, i.e., $q$ is surjective and $\ker q$ is a central subspace of $\widehat{\mathfrak{g}}$. We pick an element $\hat{E} \in \widehat{\mathfrak{g}}$ with $q(\hat{E}) = E$. Then $\text{ad} \hat{E}$ is diagonalizable with the eigenvalues $\{\pm 1, 0\}$ and defines a 3-graded

$$\widehat{\mathfrak{g}} = \widehat{\mathfrak{g}}_+ \oplus \widehat{\mathfrak{g}}_0 \oplus \widehat{\mathfrak{g}}_-$$

such that $q$ is a morphism of 3-graded Lie algebras.

Proof. First we observe that $q \circ \text{ad} \hat{E} = \text{ad} E \circ q$. From the relation $(\text{ad} E)^3 = \text{ad} E$ we derive that

$$0 = ((\text{ad} E)^3 - \text{ad} E) \circ q = q \circ ((\text{ad} E)^3 - \text{ad} \hat{E}),$$

and hence that

$$(\text{ad} \hat{E})^3 - \text{ad} \hat{E}) \subseteq \ker q \subseteq \mathfrak{z}(\widehat{\mathfrak{g}}).$$

Applying $\text{ad} \hat{E}$, we see that

$$(\text{ad} \hat{E})^4 = (\text{ad} \hat{E})^2,$$

i.e.,

$$(\text{ad} \hat{E})^2(\text{ad} \hat{E} - 1)(\text{ad} \hat{E} + 1) = 0.$$ 

Let

$$\widehat{\mathfrak{g}} = \widehat{\mathfrak{g}}_+ \oplus \widehat{\mathfrak{g}}_0 \oplus \widehat{\mathfrak{g}}_1$$

be the generalized eigenspace decomposition for $\text{ad} \hat{E}$. Then

$$\text{ad} \hat{E}_{| \widehat{\mathfrak{g}}_{\pm}} = \pm id_{\widehat{\mathfrak{g}}_{\pm}} \quad \text{and} \quad (\text{ad} \hat{E})^2 \widehat{\mathfrak{g}}_0 = \{0\}.$$ 

From $\ker q \subseteq \mathfrak{z}(\widehat{\mathfrak{g}}) \subseteq \widehat{\mathfrak{g}}_0$, we derive that $q_{| \widehat{\mathfrak{g}}_{\pm}}$ is injective and maps $\widehat{\mathfrak{g}}_{\pm}$ bijectively onto $\mathfrak{g}_{\pm}$. Therefore $\mathfrak{g}_0 = \mathfrak{z} \mathfrak{E} + [\mathfrak{g}_+, \mathfrak{g}_-]$ leads to

$$\widehat{\mathfrak{g}}_0 = q^{-1}(\mathfrak{g}_0) = \ker q + \mathfrak{z} \mathfrak{E} + [\widehat{\mathfrak{g}}_+, \widehat{\mathfrak{g}}_-].$$

As $[\widehat{\mathfrak{g}}_+, \widehat{\mathfrak{g}}_-] \subseteq \ker \text{ad} \hat{E}$, we conclude that

$$\widehat{\mathfrak{g}}_0 \subseteq \ker \text{ad} \hat{E},$$

and hence that $\hat{E}$ is a grading element for the 3-grading $\widehat{\mathfrak{g}} = \widehat{\mathfrak{g}}_+ \oplus \widehat{\mathfrak{g}}_0 \oplus \widehat{\mathfrak{g}}_-$. \qed

7.3. If $\mathfrak{g}$ is 3-graded with grading element $E$ and $\mathfrak{z} \subseteq \mathfrak{g}$ is a central subspace, then $\mathfrak{z} \subseteq \ker \text{ad} E \cong \mathfrak{g}_0$, and the quotient map $q: \mathfrak{g} \to \mathfrak{g}/\mathfrak{z}$ is a central extension which is a morphism of 3-graded Lie algebras.

This implies that for a central extension $q: \widehat{\mathfrak{g}} \to \mathfrak{g}$ for which $\widehat{\mathfrak{g}}$ is 3-graded with grading element $\hat{E}$, the Lie algebra $\mathfrak{g}$ is 3-graded with grading element $E := q(\hat{E})$, and Lemma 7.2 provides the converse information, that if $\mathfrak{g}$ is 3-graded with grading element $E$ and generated by $E$ and $\mathfrak{g}_\pm$, then the Lie algebra $\widehat{\mathfrak{g}}$ has a natural 3-grading defined by an element $\hat{E}$ with $q(\hat{E}) = E$ and $q$ is a morphism of 3-graded Lie algebra. Passing to the subalgebra generated by $\hat{E}$ and $\mathfrak{g}_\pm$, we even obtain a 3-grading satisfying the same condition as $\mathfrak{g}$. In fact, $\mathfrak{h} := \widehat{\mathfrak{g}}_+ + \widehat{\mathfrak{g}}_- + [\widehat{\mathfrak{g}}_+, \widehat{\mathfrak{g}}_-] + \mathfrak{z} \mathfrak{E} \subseteq \widehat{\mathfrak{g}}$ is a 3-graded subalgebra with $q(\mathfrak{h}) = \mathfrak{g}$, so that $\mathfrak{g} \subseteq \mathfrak{h} + \ker q \subseteq \mathfrak{h} + \mathfrak{z}(\widehat{\mathfrak{g}})$. In particular, $\mathfrak{h}$ is an ideal of $\widehat{\mathfrak{g}}$.

These considerations show that to understand central extensions of 3-graded Lie algebras, a natural context is given by those central extensions $q: \widehat{\mathfrak{g}} \to \mathfrak{g}$ which are morphisms of 3-graded Lie algebras with grading element satisfying (7.1).
Lemma 7.4. Let \( q \colon \widehat{g} \to g \) be a central extension of 3-graded Lie algebras with grading elements \( \widehat{E} \) and \( E = q(\widehat{E}) \) satisfying (7.1). Then

\[
q^{-1}(\widehat{j}(g)) = \widehat{j}(g)
\]

and therefore \( g/\widehat{j}(g) \cong \widehat{g}/\widehat{j}(g) \).

Proof. Since \( q \) is surjective, we have \( \widehat{j}(g) \subseteq q^{-1}(\widehat{j}(g)) \). If, conversely, \( q(x) \in \widehat{j}(g) \), then \( [x, \widehat{g}] \subseteq \ker q \subseteq \widehat{j}(g) \subseteq \widehat{g}_0 \). In particular, we obtain \( [x, \widehat{E}] \in \widehat{g}_0 \) and therefore \( x \in \widehat{g}_0 \). This in turn implies \( [x, \widehat{g}_\pm] \subseteq \widehat{g}_\pm \). As \( q |_{\widehat{g}_\pm} \) is injective, \( [x, \widehat{g}_\pm] \subseteq \ker q \cap \widehat{g}_\pm = \{0\} \). Therefore \( x \) commutes with \( \widehat{g}_\pm \) and \( \widehat{E} \), hence is central because \( \widehat{g} \) is generated by \( \widehat{E} \) and \( \widehat{g}_\pm \).

Corollary 7.5. If \( g \) satisfies (7.1), then \( \widehat{j}(g/\widehat{j}(g)) = \{0\} \).

Proof. The adjoint representation \( \text{ad} \colon g \to \text{ad} \ g \cong g/\widehat{j}(g) \) is a central extension satisfying the assumptions of Lemma 6.3. Therefore \( \ker \text{ad} = \widehat{j}(g) = \text{ad}^{-1}(\widehat{j}(g)) \) implies \( \widehat{j}(\text{ad} g) = \{0\} \).

Remark 7.6. (a) Let \( g \) a 3-graded Lie algebra with grading element \( E \) and \( \widehat{g} \cong g \) the ideal \( \widehat{g} \) generated by \( E \) and \( g_{\pm} \) (see Section 6.5). We consider the Lie algebra homomorphism

\[
\text{ad} \colon g \to \text{der}(g), \quad x \mapsto \text{ad} x|_g.
\]

In view of Corollary 7.5, \( (\text{ad})|_{g/\widehat{j}(g)} \cong \text{ad} g \cong g/\widehat{j}(g) \) is a center-free 3-graded Lie algebra satisfying (7.1).

(b) If \( g \) is a center-free 3-graded Lie algebra satisfying (7.1) and \( (V^+, V^-) = (g_+, g_-) \) is the corresponding Jordan pair, then the representation

\[
\text{ad}_{V^\pm} \colon g_0 \to \text{der}(V^+, V^-), \quad x \mapsto (\text{ad} x|_{V^+}, \text{ad} x|_{V^-})
\]

is injective, and

\[
g \to V^+ \oplus \text{der}(V^+, V^-) \oplus V^-, \quad x_+ + x_0 + x_- \mapsto (x_+, \text{ad}_{V^+} x_0, x_-)
\]

is an embedding of Lie algebras, where the right hand side carries the bracket defined in Section 3.1. On the other hand, the subalgebra of \( g \) generated by \( g_{\pm} \) is isomorphic to the corresponding subalgebra of \( V^+ \oplus \text{der}(V^+, V^-) \oplus V^- \), which is \( \text{TKK}(V^+, V^-) \).

Definition 7.7. Let \( g \) be a Lie algebra. We write \( \langle g, g \rangle \) for the quotient of \( \Lambda^2(g) \) by the subspace generated by the elements of the form

\[
[x, y] \wedge z + [y, z] \wedge x + [z, x] \wedge y,
\]

and write \( \langle x, y \rangle \) for the image of \( x \wedge y \) in \( \langle g, g \rangle \). Then \( \langle g, g \rangle \) carries a natural Lie algebra structure satisfying

\[
[(x, y), (x', y')] = \{[x, y], [x', y']\},
\]

and the map

\[
b_g : \langle g, g \rangle \to g, \quad \langle x, y \rangle \mapsto [x, y]
\]

is a homomorphism of Lie algebras.
Projective completions of Jordan pairs

**Theorem 7.8.** Suppose that \( \mathfrak{g} \) is 3-graded with grading element \( E \) satisfying (7.1). If \( \mathfrak{g} \) is perfect, then we put \( \mathfrak{g} := (\mathfrak{g}, \mathfrak{g}) \), and if \( \mathfrak{g} \) is not perfect, then we define

\[
\tilde{\mathfrak{g}} := (\mathfrak{g}, \mathfrak{g}) \times \mathbb{K}E,
\]

where \( \text{ad} \tilde{E} \) satisfies

\[
(7.2) \quad \left[ E, (x, y) \right] := \left( [E, x], y \right) + \left( x, [E, y] \right) = \left( E, [x, y] \right).
\]

Then there is a unique Lie algebra homomorphism

\[
q_{\mathfrak{g}} : \tilde{\mathfrak{g}} \to \mathfrak{g} \quad \text{with} \quad q_{\mathfrak{g}}((x, y)) = [x, y] \quad \text{and} \quad q_{\mathfrak{g}}(E) = E.
\]

This homomorphism is surjective with central kernel, hence a central extension of \( \mathfrak{g} \). Moreover, it is weakly universal in the sense that for any central extension \( q : \hat{\mathfrak{g}} \to \mathfrak{g} \) with a 3-graded Lie algebra \( \hat{\mathfrak{g}} \) with grading element \( \hat{E} \in \hat{\mathfrak{g}} \), there exists a unique Lie algebra homomorphism \( \alpha : \hat{\mathfrak{g}} \to \hat{\mathfrak{g}} \) with \( \alpha \circ \alpha = q \) and, if \( \mathfrak{g} \) is not perfect, with \( \alpha(E) = \hat{E} \).

**Proof.** First we observe that \( \mathfrak{g} = [\mathfrak{g}, \mathfrak{g}] + \mathbb{K}E \). If \( \mathfrak{g} \) is perfect, then

\[
b_{\mathfrak{g}} : \tilde{\mathfrak{g}} := (\mathfrak{g}, \mathfrak{g}) \to \mathfrak{g}
\]

is the universal central extension of \( \mathfrak{g} \). If \( \mathfrak{g} \) is not perfect, then \( E \notin [\mathfrak{g}, \mathfrak{g}] = \text{im}(b_{\mathfrak{g}}) \). Therefore \( \mathfrak{g} \cong [\mathfrak{g}, \mathfrak{g}] \times \mathbb{K}E \).

The Lie algebra \( \text{der}(\mathfrak{g}) \) acts in a natural way by derivations on \( \langle \mathfrak{g}, \mathfrak{g} \rangle \) via

\[
d(x, y) = (d, x, y) + (x, d, y).
\]

We may therefore form the Lie algebra \( \hat{\mathfrak{g}} := (\mathfrak{g}, \mathfrak{g}) \times \mathbb{K}E \), where \( \text{ad} \hat{E} \) satisfies (7.2).

In both cases we obtain quotient homomorphisms \( q_{\mathfrak{g}} : \hat{\mathfrak{g}} \to \mathfrak{g} \) with \( \ker q_{\mathfrak{g}} = \ker b_{\mathfrak{g}} \subseteq \mathfrak{g} \). From (7.2) we derive that the action of \( E \) on \( \langle \mathfrak{g}, \mathfrak{g} \rangle \) annihilates \( \ker b_{\mathfrak{g}} \), so that \( \ker q_{\mathfrak{g}} \) is central in both cases. This means that \( q_{\mathfrak{g}} \) is a central extension, and Lemma 7.2 implies that \( \hat{\mathfrak{g}} \) is 3-graded with grading element \( \hat{E} \). Moreover,

\[
\hat{\mathfrak{g}} := \hat{\mathfrak{g}}_+ + \hat{\mathfrak{g}}_- + [\hat{\mathfrak{g}}_+, \hat{\mathfrak{g}}_-] + \mathbb{K}E
\]

is an ideal of \( \hat{\mathfrak{g}} \) with \( \hat{\mathfrak{g}} + \ker q_{\mathfrak{g}} = \hat{\mathfrak{g}} \). In view of \( \langle E, E \rangle = 0 \), we have

\[
[\mathfrak{g}, \mathfrak{g}] = \langle [\mathfrak{g}, \mathfrak{g}], [\mathfrak{g}, \mathfrak{g}] \rangle + \langle E, [\mathfrak{g}, \mathfrak{g}] \rangle = \langle [\mathfrak{g}, \mathfrak{g}] \rangle + \langle [\mathfrak{g}, \mathfrak{g}], E \rangle = \langle [\mathfrak{g}, \mathfrak{g}] \rangle.
\]

Therefore \( [\mathfrak{g}, \mathfrak{g}] \subseteq \hat{\mathfrak{g}} \) implies that \( \hat{\mathfrak{g}} \) satisfies (7.1).

We claim that \( q_{\mathfrak{g}} \) is weakly universal as a central extension of 3-graded Lie algebras satisfying (7.1). So let \( \hat{\mathfrak{g}} : \hat{\mathfrak{g}} \to \mathfrak{g} \) be a central extension. Then the bracket map \( \hat{\mathfrak{g}} \times \hat{\mathfrak{g}} \to \hat{\mathfrak{g}} \) factors through an alternating bilinear map

\[
b : \mathfrak{g} \times \mathfrak{g} \to \hat{\mathfrak{g}} \quad \text{with} \quad b(q(x), q(y)) = [x, y], \quad x, y \in \hat{\mathfrak{g}}.
\]

Then the Jacobi identity in \( \hat{\mathfrak{g}} \) implies that \( b \) satisfies the cocycle condition

\[
b([x, y], z) + b([y, z], x) + b([z, x], y) = 0.
\]

Hence there exists a unique linear map

\[
\varphi : \langle \mathfrak{g}, \mathfrak{g} \rangle \to \hat{\mathfrak{g}} \quad \text{with} \quad \varphi((x, y)) = b(x, y),
\]

and it is easy to see that \( \varphi \) is a homomorphism of Lie algebras. Moreover, \( \varphi \) is a morphism of 3-graded Lie algebras, because the grading on \( \hat{\mathfrak{g}} \) is induced by the map \( x \mapsto b(E, q(x)) \). If \( \mathfrak{g} \) is not perfect, then \( \hat{\mathfrak{g}} \) is not perfect, and no grading element \( \hat{E} \in \hat{\mathfrak{g}} \) is contained in \( [\mathfrak{g}, \mathfrak{g}] \). We may therefore extend \( \varphi \) to a Lie algebra homomorphism

\[
\varphi : \hat{\mathfrak{g}} \to \hat{\mathfrak{g}} \quad \text{with} \quad \varphi(\hat{E}) = \hat{E}.
\]

This proves the weak universality of \( \hat{\mathfrak{g}} \) as a 3-graded Lie algebra with grading element \( \hat{E} \). The map \( \varphi : \hat{\mathfrak{g}} \to \hat{\mathfrak{g}} \) is not uniquely determined by the requirement that \( q \circ \varphi = q_{\mathfrak{g}} \) because we may add any Lie algebra homomorphism \( \psi : \mathfrak{g} \to \ker q \), which corresponds to the ambiguity in the choice of the grading element \( \hat{E} \in \hat{\mathfrak{g}} \). Note that the commutator algebra of \( \hat{\mathfrak{g}} \) is a hyperplane, so that \( \psi \) is determined by \( \psi(E) \).
7.9. Central extensions have isomorphic geometries. Next we compare the groups
\[ G \subset \langle e^{ad_{\mathfrak{g}}} \rangle \subset \text{Aut}(\mathfrak{g}) \quad \text{and} \quad \hat{G} \subset \langle e^{ad_{\mathfrak{g}}} \rangle \subset \text{Aut}(\hat{\mathfrak{g}}), \]
where \( \mathfrak{g} \to \hat{\mathfrak{g}} \) is a central extension of 3-graded Lie algebras satisfying (7.1). Since each element of \( \hat{G} \) fixes the kernel \( \mathfrak{j} \) := ker\( q \) pointwise, it induces an automorphism of \( \mathfrak{g} \), and we thus obtain a group homomorphism
\[ q_G \colon \hat{G} \to G \quad \text{with} \quad q_G(g) \circ q = q \circ g, \quad g \in \hat{G}, \]
because \( e^{ad_{\mathfrak{g}}} \) is mapped onto \( e^{ad_{\mathfrak{g}}} \). The following theorem provides a short direct argument for the isomorphism of the geometries associated to central extensions. Since the corresponding Jordan pairs are the same, this could also be deduced from the general result mentioned in Section 6.2.

**Theorem 7.10.** We have \( q_G^{-1}(H) = \hat{H} \) and \( q_G^{-1}(P^\pm) = \hat{P}^\pm \). For the corresponding homogeneous spaces, we have
\[ \hat{G}/\hat{P}^\pm \cong G/P^\pm \quad \text{and} \quad \hat{G}/\hat{H} \cong G/H \]
as homogeneous spaces of \( \hat{G} \).

**Proof.** Since \( q_G \) maps a generating subset of \( \hat{G} \) onto a generating subset of \( G \), it is surjective. First, we observe that for any \( h \in \hat{G} \) we have
\[ q_G(h).E - E = q(h.E - \hat{E}). \tag{7.3} \]
If \( h \in \hat{H} \), then \( h.E - \hat{E} \in \mathfrak{j}(\hat{\mathfrak{g}}) \), and (7.3) leads to
\[ q_G(h).E - E = q(h.E - \hat{E}) \in q(\mathfrak{j}(\hat{\mathfrak{g}})) = \mathfrak{j}(\mathfrak{g}), \]
and hence \( q_G(h) \in H \). Suppose, conversely, that \( q_G(h) \in H \). Then (7.3) implies
\[ h.E - \hat{E} \in q^{-1}(\mathfrak{j}(\mathfrak{g})) = \mathfrak{j}(\mathfrak{g}), \]
so that \( h \in \hat{H} \).

Since \( \hat{P} = \hat{H}\hat{U}^\pm \) and \( q_G(\hat{U}^\pm) = U^\pm \), we have
\[ q_G^{-1}(P^\pm) = q_G^{-1}(H)\hat{U}^\pm \subset \hat{H}\hat{U}^\pm = \hat{P}^\pm. \]

Further, \( q_G(\hat{P}^\pm) = q_G(\hat{H})q_G(\hat{U}^\pm) \subset HU^\pm = P^\pm \), and we obtain \( q_G^{-1}(P^\pm) = \hat{P}^\pm \).

For the homogeneous spaces, we now get
\[ G/P^\pm \cong \hat{G}/q_G^{-1}(\hat{P}^\pm) = \hat{G}/\hat{P}^\pm \quad \text{and} \quad G/H \cong \hat{G}/q_G^{-1}(\hat{H}) = \hat{G}/\hat{H}. \]

**Remark 7.11.** We take a closer look at the kernel of \( q_G \). Let \( g \in \ker q_G \subset \hat{H} \). Then \( g \) preserves the grading of \( \hat{\mathfrak{g}} \). Since \( q \big|_{\mathfrak{g}_0} \) is injective, we conclude that \( g \big|_{\mathfrak{g}_0} = \text{id}_{\mathfrak{g}_0} \), and hence that \( g - \text{id}_{\mathfrak{g}_0} \) vanishes on the subalgebra generated by \( \mathfrak{g}_\pm \). Moreover, \( \text{im}(g - \text{id}_{\mathfrak{g}_0}) \subset \ker q = \mathfrak{j} \), so that
\[ g = 1 + D, \]
where \( D \colon \mathfrak{g} \to \mathfrak{j} \) is a linear map. As \( g \) is an automorphism, it follows that \( D \in \text{der}(\mathfrak{g}) \), and hence that \( \mathfrak{g}_0, \mathfrak{g}_\pm \subset \ker D \). If \( \mathfrak{g} \) is perfect, then \( D \) vanishes, but if \( \hat{E} \notin [\hat{\mathfrak{g}}, \hat{\mathfrak{g}}] \), then
\[ \text{Hom}_{\text{Lin}}(\mathfrak{j}, \mathfrak{j}) = \text{Hom}(\mathbb{R}\hat{E}, \mathfrak{j}) \cong \mathfrak{j} \]
describes the possibilities for \( D \), which is determined by \( D(\hat{E}) \in \mathfrak{j} \).

Since, for \( h \in \hat{H} \) and \( v \in \mathfrak{g}_\pm \), we have \( he^{ad_v}h^{-1} = e^{ad_{hv}} \), the condition \( g \big|_{\mathfrak{g}_\pm} = \text{id}_{\mathfrak{g}_\pm} \) implies that \( h \) commutes with the generating subset \( e^{ad_{\mathfrak{g}_\pm}} \), and hence that
\[ \ker q_G \subset Z(\hat{G}). \]
This means that \( q_G \colon \hat{G} \to G \) is a central extension of groups. ■
Example 7.12. We consider the case of a trivial Jordan pair $(V^+, V^-)$, i.e., all the maps $T^\pm$ vanish. Then the corresponding 3-graded Lie algebra is the semidirect sum

$$g = (V^+ \oplus V^-) \rtimes \mathbb{K}E,$$

where

$$[E, (v_+, v_-)] = (v_+, -v_-) \quad \text{and} \quad [V^+, V^-] = \{0\}.$$ Let $\beta : V^+ \times V^- \to \mathfrak{g}$ be any bilinear map. Then

$$\omega((v_+, v_-, \lambda E), (w_+, w_-, \mu E)) := \beta(v_+, w_-) - \beta(v_-, w_+)$$

is a Lie algebra cocycle which defines a central extension

$$\hat{\mathfrak{g}} = \mathfrak{g} \oplus \mathfrak{z}$$

with the bracket

$$[(z, z'), (z', z'')] := ([z, z'], \omega(z, z')) , \quad z, z' \in \mathfrak{g}, z, z' \in \mathfrak{z}.$$ The subalgebra of $\hat{\mathfrak{g}}$ generated by $V^\pm$ is 2-step nilpotent and $\hat{\mathfrak{g}}$ is solvable. In $\hat{\mathfrak{g}}$ we have

$$[\mathrm{ad} V^+, \mathrm{ad} V^-] = [V^+, V^-] \subseteq \mathrm{ad} \mathfrak{z} = \{0\},$$

so that the groups $\hat{G}$ and $G$ are both abelian. Considering the orbit of the grading element, it is easy to see that

$$\hat{G} \cong V^+ \rtimes V^- \cong G.$$  

Remark 7.13. Let $\mathfrak{g}$ be a 3-graded Lie algebra with grading element $E$. We have seen in Chapter 5 that the homogeneous spaces $G/H$ and $G/P^\pm$ are isomorphic to those associated to the subalgebra $\mathfrak{g}_\pm$ generated by $E$ and $\mathfrak{g}_\pm$. Furthermore, the results in this section imply that the same holds for the homogeneous spaces associated to the center-free Lie algebra $\mathfrak{g}/3(\mathfrak{g})$. The latter Lie algebra is isomorphic to the Tits–Kantor–Koecher Lie algebra

$$\mathrm{TKK}(\mathfrak{g}_+, \mathfrak{g}_-) = \mathfrak{g}_+ \oplus (\mathrm{id} \mathfrak{g}_+ + \mathbb{K}E) \oplus \mathfrak{g}_-$$

doing the Jordan pair $(\mathfrak{g}_+, \mathfrak{g}_-)$. For that we only have to observe that the triviality of the center implies that $\mathfrak{g}/3(\mathfrak{g})$ embeds into $\mathrm{der}(\mathfrak{g}_+, \mathfrak{g}_-)$. We therefore obtain a natural identification of the homogeneous space $G/H$ and $G/P^\pm$ with a space of 3-gradings of $\mathrm{TKK}(\mathfrak{g}_+, \mathfrak{g}_-)$, resp., a space of filtrations of this Lie algebra.

8. Grassmannian geometries and associative structures

8.1. Grassmannian geometries. Let $R$ be an associative algebra with unit $1$ over the commutative unital ring $\mathbb{K}$ and let $V$ be a right $R$-module. The complemented Grassmannian (of $V$ over $R$) is the space

$$\mathcal{C} := \{E \subset V : \exists F : V = E \oplus F \quad (E, F : \text{submodules of } V)\}$$

of $R$-submodules of $V$ that have a complement. For $V = R$ this is the space of complemented right ideals of $R$ (cf. Section 8.6 below). For $E, F \in \mathcal{C}$ we write $E \uparrow F$ if $V = E \oplus F$; we let $E^\perp = \{F \in \mathcal{C} : F \uparrow E\}$ be the set of complementary submodules of $E$ and

$$(\mathcal{C} \times \mathcal{C})^\perp = \{(E, F) \in \mathcal{C} \times \mathcal{C} : V = E \oplus F\}.$$ (8.2)

Let

$$\mathcal{P} := \{p \in \mathrm{End}_R(V) : p^2 = p\} = \mathrm{Idem}(\mathrm{End}_R(V))$$

be the space of projectors, resp., idempotents in $V$. Taking $I := 2p - \mathrm{id}_V$ instead of $p$, we may also work with the condition $I^2 = \mathrm{id}_V$ instead of $p^2 = p$ and view $\mathcal{P}$ as the space of polarizations of $V$. In this framework, the following analog of Theorem 1.6 is an easy exercise in Linear Algebra:
Proposition 8.2. 
(i) The map $\mathcal{P} \to (\mathcal{C} \times \mathcal{C})^\top$, $p \mapsto (\text{im}(p), \ker(p)) = (\text{im}(p), \text{im}(1 - p))$ is a bijection. 
(ii) For all $E \in \mathcal{C}$, $E^\top$ carries canonically the structure of an affine space over $\mathbb{K}$ (not over $R$ in general), modeled on the $\mathbb{K}$-module $\text{Hom}_R(V/E, E)$.

Moreover, $\mathcal{P}$ clearly is stable under the binary map $\mu$ defined by $\mu(p, q) = (2p - 1)q(2p - 1)$ which defines on $\mathcal{P}$ the structure of a reflection space (cf. 4.1). Using scalar extension by dual numbers over $\mathbb{K}$, one may also define tangent bundles of $\mathcal{P}$ and $\mathcal{C}$, and then Property (S4) will also hold for $\mu$; but we will not pursue this construction here.

8.3. Flags and elementary group. We are going to describe the relation between this simple linear algebra model and the model from Theorem 1.6. Let $\mathfrak{g} := \text{End}_R(V)$ with the usual commutator as Lie bracket. Note that the commutator is not $R$-bilinear in general, but it is bilinear over the center of $R$; hence $\mathfrak{g}$ is a $\mathbb{K}$-Lie algebra. An element $p \in \mathcal{P}$ defines a derivation $\text{ad}(p)$ of $\mathfrak{g}$ which is tripotent; with respect to the decomposition $V = E \oplus F := \text{im}(p) \oplus \ker(p)$, i.e., (in the obvious matrix notation) $p = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$, and the grading of $\mathfrak{g}$ is described by:

$$
\begin{align*}
\mathfrak{g}_{-1} &= \left\{ \begin{pmatrix} 0 & 0 \\ \alpha & 0 \end{pmatrix} : \alpha \in \text{Hom}_R(E, F) \right\}, \\
\mathfrak{g}_1 &= \left\{ \begin{pmatrix} 0 & \beta \\ 0 & 0 \end{pmatrix} : \beta \in \text{Hom}_R(F, E) \right\}, \\
\mathfrak{g}_0 &= \left\{ \begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix} : A \in \text{End}_R(E), B \in \text{End}_R(F) \right\}.
\end{align*}
$$

(8.4)

Thus we have a well-defined map from $\mathcal{P}$ to the space $\mathcal{G}$ of inner 3-gradings of $\mathfrak{g}$:

$$
\varphi: \mathcal{P} \to \mathcal{G}, \quad p \mapsto \text{ad}(p).
$$

(8.5)

On the other hand, if $E \in \mathcal{C}$, then to the “short flag” $0 \subset E \subset V$ we may associate a “long flag” $f_E : 0 \subset f_1 \subset f_0 \subset \mathfrak{g}$ by letting

$$
\begin{align*}
f_1 := \{ X \in \mathfrak{g} : X(V) \subset E, \; X(E) = 0 \} \subset f_0 := \{ X \in \mathfrak{g} : X(E) \subset E \} \subset \mathfrak{g}:
\end{align*}
$$

(8.6)

in matrix form:

$$
\begin{pmatrix} 0 & * \\ 0 & 0 \end{pmatrix} \subset \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \subset \begin{pmatrix} * & * \\ * & * \end{pmatrix}.
$$

It is clear that this is a 3-filtration of $\mathfrak{g}$ (even in an associative sense). Thus we have a well-defined map

$$
\varphi_C : \mathcal{C} \to \mathcal{F}, \quad E \mapsto f_E,
$$

(8.7)

and it follows from the definitions that the diagram

$$
\begin{array}{ccc}
\mathcal{C} \times \mathcal{C} & \supset & \mathcal{P} \\
\downarrow & & \downarrow \\
\mathcal{F} \times \mathcal{F} & \supset & \mathcal{G}
\end{array}
$$

(8.8)

commutes. All maps in this diagram are obviously equivariant with respect to the natural action of the group $\text{GL}_R(V)$ on all spaces that are involved.

If $E \in \mathcal{C}$ is fixed, then the elements $X \in f^1$ (with $f^1$ as in (8.6)) are 2-step nilpotent; thus $e^X = 1 + X$. Let

$$
U_E := e^{1 + f_1} = 1 + f_1 = \left\{ \begin{pmatrix} 1 & \beta \\ 0 & 1 \end{pmatrix} : \beta \in \text{Hom}_R(F, E) \right\},
$$

(8.9)

where the latter matrix representation is with respect to a fixed complement $F$ of $E$. The group $U_E$ acts simply transitively on the set $E^\top$ of complements of $E$. Therefore, if for such a fixed decomposition $V = E \oplus F$, we let

$$
G(E, F) := \langle U_E, U_F \rangle \subset \text{GL}_R(V)
$$

(8.10)
be the group generated by \( U_E \) and \( U_F \), called the elementary group of \((V, E, F)\), then \( G(E, F) = G(E, F') \) for any two complements \( F, F' \) of \( E \), and we may write also \( G_E \) for \( G(E, F) \). We let
\[
P_E := \{ g \in G_E : g(E) = E \},
\]
and, for a fixed complement \( F \) of \( E \),
\[
H(E, F) := \{ g \in G(E, F) : g(E) = E, g(F) = F \} = P_E \cap P_F.
\]

**Theorem 8.4.** The equivariant maps \( \varphi_P \) and \( \varphi_C \) have the following properties:

1. For all \( p \in \mathcal{C} \), \( \varphi_C(E^\top) = \varphi_C(E)^\top \).
2. For all \( p \in \mathcal{P} \), the restriction of the map \( \varphi_P \) to the orbit \( \text{GL}_R(V).p \),
\[
\mathcal{P} \supset \text{GL}_R(V).p \to \mathcal{G}, \quad g.p \mapsto \text{ad}(g.p),
\]
is injective.
3. For all \( E \in \mathcal{C} \), the restriction of the map \( \varphi_C \) to the orbit \( \text{GL}_R(V).E \),
\[
\mathcal{C} \supset \text{GL}_R(V).E \to \mathcal{F}, \quad g.E \mapsto \text{ad}(g).E,
\]
is injective.
4. Let \( p \in \mathcal{P} \) with associated decomposition \( V = E \oplus F = \text{im}(p) \oplus \ker(p) \). The map \( \varphi_P \) induces a bijection
\[
G(E, F)/H(E, F) \cong G(E, F).p \to G(\text{ad}(p)). \text{ad}(p) \cong G(\text{ad}(p))/H(\text{ad}(p)),
\]
and the map \( \varphi_C \) induces a bijection
\[
G(E, F)/P_E \cong G(E, F).E \to G(\text{ad}(p)).E = G(\text{ad}(p))/P^\perp.
\]

**Proof.** (1) The action of \( U_E \) on \( \mathfrak{g} \) is precisely the action of \( e^{\text{ad}(1)} \) on \( \mathfrak{g} \). Since \( U_E \) acts simply transitively on the set of complements of \( E \), the claim follows from the corresponding fact about \( \mathfrak{g} \) (Theorem 1.6(2)).

(2) Let \( e \in \mathcal{P} \) and \( f := ge g^{-1} \in \mathcal{P} \) with \( g \in \text{GL}_R(V) \) such that \( \text{ad}(e) = \text{ad}(f) \). Then \( z := f - e \in \text{Z}(A) \) where \( A \) is the associative \( k \)-algebra \( \text{End}_R(V) \). In particular, \( ef = fe \) and therefore
\[
(e - f)ef = e^2f - ef^2 = ef - ef = 0.
\]
We have
\[
(f - e)^2 = f^2 - 2ef + e^2 = f + e - 2ef
\]
and
\[
(f - e)^3 = (f - e)(f + e - 2ef) = f^2 - e^2 - 2(f - e)ef = f - e,
\]
i.e., \( z^3 = z \). Write \( z = z_1 - z_2 \) with
\[
z_1 = \frac{1}{2} z(z + 1) \quad \text{and} \quad z_2 = \frac{1}{2} z(z - 1).
\]
Then \( z_1 \) and \( z_2 \) are again central, and \( z_1^2 = z_1 \) and \( z_2^2 = z_2 \). This implies
\[
z_1 = \frac{1}{2} (f - e)(f - e + 1) = \frac{1}{2} (f + e - 2ef + f - e) = \frac{1}{2} (2f - 2ef) = f - ef = zf
\]
and
\[
z_2 = \frac{1}{2} (f - e)(f - e - 1) = \frac{1}{2} (f + e - 2ef - f + e) = \frac{1}{2} (2e - 2ef) = e - ef = -ze.
\]
We further obtain
\[
z_2 = -z_2 z = z_2 (e - ge g^{-1}) = z_2 e - g z_2 e g^{-1} = -ze^2 + gze^2 g^{-1} = -ze + gze g^{-1} = z_2 - g z_2 g^{-1} = 0.
\]
because \( z_2 \) is central, and likewise
\[
z_1 = z_1 z = z_1 (f - g^{-1} f g) = z_1 f - g^{-1} z_1 f g = zf^2 - g^{-1} zf^2 g = zf - g^{-1} zf g = z_1 - g^{-1} z_1 g = 0.
\]
Eventually we obtain \( z = z_1 - z_2 = 0 \) and hence \( e = f \), as had to be shown.

(3) This follows by combining (2) and (1) (observing that the fibers of the map \( \mathcal{P} \to \mathcal{C} \), \( p \mapsto \text{im}(p) \) are of the form \( F^\perp \), \( F \in \mathcal{C} \), and similarly for \( \mathcal{G} \to \mathcal{F} \)).

(4) This follows from (2) and (3), observing that the action of \( H(E, F) \) on \( \mathfrak{g} \) coincides with the action of \( H(\text{ad}(p)) \). For \( P_E \) we argue similarly. \qed
8.5. **Special Jordan pairs.** If $p \in \mathcal{P}$ and $\mathfrak{g} = \mathfrak{gl}(V)$, then the associated Jordan pair is

$$(\text{Hom}_R(F,E), \text{Hom}_R(E,F)), \quad T^{\pm}(X,Y,Z) = XYZ + ZYX.$$ A Jordan pair that is a sub-pair of such a pair is called special. The Bergman operator is in this case given by

$$B(X,Y) = (1 - XY)Z(1 - YX).$$

The special case where $V = E \oplus E$ gives rise to a self-dual geometry and is related to the $K$-Jordan algebra $\text{End}_K(E)$.

8.6. **Geometry of right ideals.** Now let us consider the case of the right $R$-module $V = R$. In this case (complemented) submodules are the same as (complemented) right ideals, and the Grassmannian geometry should be called the geometry of right ideals of $R$. Via the bijection $R \to \text{Hom}_R(R,R)$, $r \to I_r$ (left multiplication by $r$), the set $\mathcal{P}$ of projectors is identified with the set of idempotents of $R$,

$$\text{Idem}(R) := \{ e \in R : e^2 = e \}.$$ The pair $(R,e)$ with an idempotent $e$ is also called a Morita context (cf. [Lo95, Section 2.1]). In this case, our Theorem 8.4 corresponds essentially to results of Loos ([Lo95, Theorem 2.8]). The symmetric space structure on $\text{Idem}(R)$ is described in the same way as after Prop. 8.2: it is given by $\mu(e,f) = (2e - 1)f(2e - 1)$.

8.7. **Geometry of the projective line.** Another interesting case is $V = R \oplus R$, taking this decomposition as base point $p \in \mathcal{P}$. This gives rise to a self-dual geometry (belonging to $R$ seen as a Jordan algebra over $K$) which is the projective line over the ring $R$, see [He05] and the recent work [BiHa01]. The corresponding 3-graded Lie algebra is $\mathfrak{g} = \mathfrak{gl}_2(R)$, resp., its subalgebra $\mathfrak{e}_2(R)$ generated by the strict upper and lower triangular matrices.

Finally, let us remark that there exist rings $R$ such that $R \oplus R \cong R$ as right $R$-modules (e.g., take $R = \text{End}_K(V)$, where $V$ is an infinite dimensional vector space over a field $K$; then $V \cong V \oplus V$ as a vector space, and hence $R = \text{Hom}_K(V,V) \cong \text{Hom}_K(V,V \oplus V)$ as a right $R$-module), so that the cases 8.6 and 8.7 have non-empty intersection.
